111 Conflict of Interest:

112 **Work Group Disclosures:**

113 Dr. Abraham: Grant support from Amgen; Honoraria from ClinGen, NIH, and ClearView;  
114 Deputy Editor of Journal of Immunology; and Clinical Immunology Society committee member.  
115 Dr. Ballow: Consultant for Pharming, Green Cross, Immune Deficiency Foundation, CSL  
116 Behring; Honorarium from UpToDate; Syneos Health Data Safety Monitoring Board for Glaxo  
117 Smith Kline; Speaker for CSL Behring, ADMA. Dr. Barnettler: Consultant for CSL Behring;  
118 Advisory Board for CSL Behring, OctaPharma; Speaker for OctaPharma; Grant support from  
119 Bristol Myers Squibb. Dr. Broderick: Clinical trial support from Novartis; Speaker for SOBI.  
120 Dr. Butte: Advisory board for ADMA; Grant support from X4, Pharming; Consultant for  
121 Pharming; Speaker for Grifols. Dr. Chan: Advisory board for SOBI; Grant support from NIH,  
122 Jeffrey Modell Foundation. Dr. Chandrakasan: Advisory board and honoraria from SOBI,  
123 Pharming, Amgen, X4; Speaker for X4. Dr. Chen: Consultant for Immune Deficiency  
124 Foundation; Advisory board for Amgen, Pharming. Dr. Chinen: Associate Editor for Journal of  
125 Allergy and Clinical Immunology. Dr. Chinn: Consultant for UpToDate; Working Group and  
126 Expert Panel Co-Chair for Clinical Genome Resource. Dr. Connelly: Advisory Board for  
127 Pharming; Honorarium from Elsevier. Dr. Danziger-Isakov: Royalties from Elsevier; Consultant  
128 for Astellas, Kamada; Clinical research support (institution) from Ansun BiPharma, AiCuris,  
129 Merck, Takeda; Past Chair of Disease Transmission Advisory Committee of Organ Procurement  
130 and Transplantation Network. Dr. Dorsey: Contributor to UpToDate. Dr. Dulek: Non-salary  
131 grant support from Eurofins-Viracor. Dr. Dutmer: Advisory Board for Amgen, Pharming;  
132 Executive Committee of Colorado Allergy & Asthma Society; Treasurer Aspen Allergy  
133 Conference; RSL Regional Governor AAAAI. Dr. Dvorak: Consultant for Alexion, UpToDate.  
134 Dr. Farmer: Consultant for Pharming. Grant support from Pharming, Bristol Myers Squibb. Dr.  
135 Forbes Satter: Consultant for Sanofi, Takeda, Grifols, Teva; Advisory Board for CSL, Takeda,  
136 Grifols; Grant support from Grifols, Immune Deficiency Foundation; CIS President-Elect. Dr.  
137 Frazer-Abel: Consultant for Adverum. Dr. Heimall: Royalties from UpToDate; Grant support  
138 from CSL Behring, Sumitomo, ADMA, Regeneron; Speaker for CSL Behring; Consultant for  
139 CSL Behring, Sumitomo; Medical Advisory Board for Jobs Research Foundation. Dr. Horner:  
140 AAAAI ITE, ADCT, and PDT committees. Dr. Keller: Consultant for Chiesi, M3 Global  
141 Research, Wolters-Kluwer; Honoraria from Chiesi, M3 Global Research, Wolters-Kluwer. Dr.  
142 Knight: Consultant for ICON, Cerus; Speaker for Beckman Coulter; Past President Association  
143 of Medical Laboratory Immunologists; CIS member; Editor Journal of Allergy and Clinical  
144 Immunology; Section Editor UpToDate; Education Committee American Association of  
145 Immunologists. Dr. Lawrence: Advisory Board for Pharming, Pharmacosmos; Grant support  
146 (institution) from NIH/NIAID, Regeneron, Takeda, Jeffrey Modell Foundation; CIS Councilor,  
147 Secretary/Treasurer; AAAAI Primary Immunodeficiency Committee Member; ACAAI Clinical  
148 Immunology & Autoimmune Diseases Committee, Special Advisor. Dr. Lehman: Advisory  
149 board for Sanofi; Grant support (institution) from Sanofi, Novartis; AAAAI ITE and PID  
150 committee member, Program Directors Assembly Councilor. Dr. Leiding: Stock in Bluebird  
151 Bio; Speaker for Grifols, SOBI; Consultant for Rocket Pharma, Prime Medicine; DSMB for  
152 Prime Medicine; Advisory board for SOBI, Amgen; Grant support from SOBI. Dr. Maglioni:  
153 Speaker for Takeda; Advisory board for Pharming. Dr. Myers: Clinical trial support from  
154 Incyte, Elixirgen Therapeutics; Medical advisory board for Team Telomere, Shwachman  
155 Diamond Syndrome Foundation; Co-Director Shwachman Diamond Syndrome Registry. Dr.  
156 Nandakumar: Secretary-Elect, Association of Medical Laboratory Immunologists; Executive  
157 officer, Association for Diagnostics & Laboratory Medicine. Dr. Orange: Consultant for Grifols,  
158 Takeda; Scientific advisory board for ADMA Biologics; Editor/Author UpToDate; Grant support

159 (institution) ADMA Biologics; Medical Advisor Jeffrey Modell Foundation. Dr. Patel:  
160 Consultant for Takeda, Janssen; Advisory board for Amgen; Speaker for Grifols, AAP, ACAAI,  
161 Amgen, Pharming, Takeda, X4 Pharma; Grant support from Takeda, ACAAI. Dr. Perez:  
162 Consultant for Grifols, CSL Behring, ADMA; Advisory board for Grifols, CSL Behring,  
163 ADMA; Speaker for Grifols, CSL Behring, ADMA; Member of AAAAI, FAAIS, CIS. Dr. Platt:  
164 Royalties from UpToDate; Expert witness for Department of Justice Vaccine Injury  
165 Compensation Program; Employment (spouse) by Quest Diagnostics; Executive committee  
166 member of Immunology Clinical Domain Working Group - Antibody Deficiencies and Primary  
167 Immune Regulatory Disorders for Clin Gen. Dr. Puck: Consultant (spouse) for Illumina;  
168 Contributor/Editor for UpToDate; Expert for California Dept of Public Health; Educational grant  
169 support (institution) from NIH; Grant support (institution) from NIH, CA Institute for  
170 Regenerative Medicine. Dr. Rider: Royalties from Wolters Kluwer; Associate Editor Journal of  
171 Clinical Immunology; Consultant for Takeda, Grifols, Pharming, X4 Pharmaceuticals; Grant  
172 support from NIH/NIAID, CDC/Jeffrey Modell Foundation, Takeda. Dr. Sacco: Speaker for  
173 Pharming. Dr. Walter: Consultant for Takeda, Cheisi, Pharming, GenPharm; Advisory Board  
174 for Takeda, Cheisi, Pharming; Speaker for Pharming, Takeda, GenPharm; Grant support from  
175 X4 Pharmaceuticals, Orca Bio, Takeda, Grifols, Cheisi, ADMA, Octapharma, Bristol-Myers  
176 Squibb. Dr. Williams: Consultant for Blueprint, Amgen, ADMA Biologics; Advisory Board for  
177 Blueprint, Genentech; Speaker for Pharming, Amgen; Advisory board for Pharming; Clinical  
178 trial grant support (institution) from Glaxo Smith Kline, ADMA Biologics, Cogent, AstraZeneca.  
179 Nothing to disclose: Drs. Chang, de la Morena, DiGiacomo, Dimitriades, Freeman, Joshi, Khan,  
180 Kitcharoensakkul, Kobrynski, Pai, and Risma.

181

182 The JTFPP members' conflict of interest disclosure forms can be found at  
183 [www.allergyparameters.org](http://www.allergyparameters.org)

184 Dr. Abrams: Nothing to disclose. Dr. Bernstein: Consultant for Novartis, Genentech, Sanofi  
185 Regeneron, Allakos, Celldex, Jasper, Escient/Incyte, Blueprint, Cogent, ARS, Guidepoint;  
186 Advisory Board for Novartis, Genentech, Sanofi Regeneron, Celldex; Grant support from  
187 Novartis, Genentech, Sanofi Regeneron, Allakos, Celldex, Jasper, Escient/Incyte, Blueprint,  
188 Cogent; AAAAI Board of Directors, AAAAI Foundation Chair, AFI Executive Vice President,  
189 Interama Vice President, WAO Board of Directors, ACARE/UCARE/ADCARE/ANACARE  
190 Director of COE, GINA Council Member, AIM COE Co-director. Dr. Chu: Grant support from  
191 AAAAI Foundation Faculty Development Award; Grant support (institution) from Canadian  
192 Institutes of Health Research, Ontario Ministry of Health and Long-Term Care/Ontario Medical  
193 Association, Health Canada (Government of Canada); GRADE Working Group Member. Dr.  
194 Ellis: Speaker for ALK Abello, AstraZeneca, Glaxo Smith Kline, Novartis, Amgen, Bausch  
195 Health, Regeneron, Sanofi; Consultant for Regeneron. Dr. Golden: Consultant for Kokua,  
196 ThermoFisher, CellDex, Aquestive, Novartis; Speaker for ARS; Royalties from UpToDate;  
197 Editorial Board for Journal of Allergy Clinical Immunology In Practice, Annals of Allergy  
198 Asthma Immunology. Dr. Greenhawt: Consultant for Aquestive; Advisory board for DBV  
199 Technologies, Takeda, Grifols, Nutricia, Novartis, Aquestive, Allergy Therapeutics,  
200 AstraZeneca, ALK-Abello, Bryn, Genentech, Protas; Speaker for Genentech, ARS; Unpaid  
201 member of scientific advisory council for National Peanut Board and medical advisory board of  
202 International Food Protein Induced Enterocolitis Syndrome Association; Brighton Collaboration  
203 Criteria Vaccine Anaphylaxis 2.0 working group member; Senior associate editor Annals of

Allergy, Asthma, and Immunology; Honoraria from Red Nucleus, Medscape, MJH Communications, Paradigm Medical Communications, Kaplan, Food Allergy Research and Education, and multiple state/local allergy societies. Dr. Ledford: Consultant for Amgen, AstraZeneca; Honoraria from AAAAI, Wolters Kluwer, ECHO CME; Grant support from AstraZeneca; Legal testimony fees; Speaker for Regeneron, Sanofi, Glaxo Smith Kline, AstraZeneca. Dr. Lieberman: Consultant for ARS, Aquestive, Bryn, Celldex, Abbvie, Amgen, Novartis, Genentech, Theravia; Advisory Board for Aquestive, Bryn; Grant support (institution) from DBV; Author for ARS, Aquestive, Bryn, DBV; Associate Editor of Annals of Allergy, Asthma, and Immunology; ACAAI Annual Meeting Program Committee Chair, Food Allergy Chair, Yardstick Committee Chair; ABAI Executive Board Member. Dr. Mosnaim: ABAI Board of Directors Member, Co-Chair Continuous Assessment Program Examination Committee, Chair Nominating Committee; Advisory Board for Chiesi, Jasper, Novartis, Sanofi, Regeneron, Astra Zeneca, Genentech; Consultant for Chiesi, Jasper, Novartis, Sanofi, Regeneron, Astra Zeneca, Genentech; Grant support (institution) from Aretia, Incyte, Teva, Glaxo Smith Kline, Novartis, Sanofi, Regeneron, Astra Zeneca, Genentech; Fellow of AAAAI, ACAAI, Illinois Society of Allergy Asthma and Immunology Dr. Rank: Royalties from UpToDate, Mayo Ventures; AAAAI Committee Member, FDA PADAC Committee Member. Dr. Shaker: Speaker for Local and Regional Allergy Society; Honoraria from Local and Regional Allergy Society; Associate Editor ACAAI; AAAAI Board of Directors; Editorial Board for Journal of Food Allergy, Journal of Allergy and Clinical Immunology In Practice. Dr. Wang: Advisory Board for FARE, Novartis; Clinical trial support (institution) from Aimmune, DBV, Siolta, NIH; Author for UpToDate; AAAAI AMPC Chair.

Resolving Conflicts of Interest: The JTFPP is committed to ensuring that the Practice Parameters are based on the best scientific evidence at the time of publication and that such evidence is free of commercial bias to the greatest extent possible. (<https://www.allergyparameters.org/parameter-and-guideline-development-process/>) The JTFPP recognizes that experts in a field may have interests that could create a potential conflict of interest (COI) with the development of a completely unbiased and objective practice parameter. To take advantage of their expertise, a process has been developed to acknowledge potential COI and attempt to prevent them from influencing the final document in a negative way. The disclosure and management of potential conflicts for all participants were conducted in accordance with JTFPP policies. To preserve the greatest transparency regarding potential COI, all members of the JTFPP and the practice parameters workgroups complete a standard potential COI disclosure form before the development of each document. During the review process, there are additional measures to avoid bias. At the workgroup level, all the sections are reviewed by all workgroup members to ensure that content is appropriate and without apparent bias. In addition, the entire document is then reviewed by the JTFPP, and any apparent bias is removed at that level. At the time of appointment, there were not any workgroup members with conflicts of interest as defined and judged by JTFPP (ie, no current material interest in any commercial entity with a product that could be affected by the guidelines). No new disclosure of new interests or relationships occurred during the development process. The final document and all recommendations are reviewed and approved by the workgroup and JTFPP. In a final stage of review, the practice parameter is sent to invited expert reviewers, selected by the AAAAI and the American College of Allergy, Asthma, and Immunology (ACAAI). The document is also posted on the AAAAI and ACAAI (and CIS for this parameter) websites for general membership and

250 the public-at-large to review and offer comment. Reviewers are also asked to provide statements  
251 of potential COI. Although the JTFPP has the final responsibility for the content of the  
252 documents submitted for publication, each reviewer's comment is discussed, and reviewers  
253 receive written responses to comments when appropriate.

254

DRAFT

## PREFACE. What is New

The Joint Task Force on Practice Parameters (JTFPP) was commissioned by the American Academy of Allergy, Asthma and Immunology (AAAAI) and the American College of Allergy, Asthma and Immunology (ACAAI) in 1989 to develop guidelines for the clinical practice of allergy and clinical immunology reflecting current evidence-based practices and clinical consensus, and to provide periodic updates. The first practice parameter for primary immunodeficiencies was developed and published in 1995.<sup>1</sup> The publication was 13 printed pages long with 47 references. It focused on the assessment of immunological function with management limited to intravenous immunoglobulins for antibody deficiencies and bone marrow transplantation for severe cellular immunodeficiencies. Subsequent updates were published in 2005 and 2015 and were 63 and 98 printed pages, respectively with 530 and 768 references.<sup>2, 3</sup> These versions expanded upon the diagnosis and care of patients with primary immunodeficiencies.

Reports of several genetic defects resulting primarily in autoimmunity and inflammatory symptoms with or without immune deficiency provided the justification for the International Union of Immunological Societies (IUIS) committee to coin the term Inborn Errors of Immunity (IEI) for all congenital disorders that primarily affect immune function, including primary immunodeficiencies. The field of IEI has grown substantively over the past decade and continues to expand. Considering the large number of publications related to the care of patients with IEI, it would be unwieldy to provide all available information in a practice parameter. The guiding principle for this practice parameter update was to present the best evidence-based recommendations to support practice, while avoiding being encyclopedic or becoming a textbook. In this update, several sections utilize tables to outline some disease specific recommendations rather than discussing each one individually in the text, while providing key references. This conveys guidelines for diagnosis and management highlighting specific examples, as well as exceptions. Broadly, the document is divided into diagnostic (1-7) and management (8-14) sections. **(Figure 1)**

New topics of importance to improving the care of patients with IEI are included. Since the last practice parameters in 2015, there have been significant advances in genetic testing and identification of novel pathogenic gene variants causing IEI. Genetic testing has also become widely available, in part due to its decreasing cost.

As in previous practice parameters on IEI, the current sections on diagnosis and management of antibody deficiencies include statements more specific than those discussed for other IEI disorders, consistent with the larger proportion of patients in these categories and the high number of available publications relative to other IEI. Because of the implementation of universal newborn screening for severe combined immunodeficiency (SCID), guidance for prompt management of infants with abnormal

screening tests is included. Specific protein antibody deficiency with recurrent infections is being introduced as a diagnosis for those patients with adequate serum IgG levels and absent response to antigens other than polysaccharides. Targeted therapy or precision medicine for IEI based on immunopathogenesis has changed the landscape of therapies for these disorders over the last decade. Thus, Section 13 is focused upon therapies that have been shown to be effective for many IEI. The last section discusses the use of tools to measure patient reported outcomes and quality of life (QoL). Several statements refer to the importance of consulting a clinician with expertise in the care of IEI. Expertise is defined as clinical training in IEI and providing care to patients with IEI. Of note, the JTFFP has developed a focused practice parameter for hereditary angioedema<sup>4</sup> and this condition is not included in the present document. Secondary immunodeficiencies constitute a growing area of clinical knowledge, with an increasing use of different therapeutic applications that modulate the immune response. Other than referring to their diagnostic evaluation, secondary immunodeficiencies are not discussed in depth in this practice parameter.

DRAFT

## GLOSSARY

*Antibody deficiency.* A condition characterized by impaired quantitative or functional antibodies.

*Combined immune deficiency.* A condition characterized by impaired T and B cell functions.

*Chromosomal microarray (CMA).* A genetic test that identifies deletions or duplications of DNA regions in the genome, also known as copy number variants (CNV).

*Immune dysregulation.* A defect in the immune system to control its reaction to microbes, other foreign substances and body tissues, resulting in excessive and/or insufficient response.

*Immunodeficiency.* A condition characterized by impaired immune responses.

*Immunorestorative therapy.* A term referring to treatments that correct the immune response, including hematopoietic stem cell transplantation (HSCT), cultured thymus tissue implantation (CTTI) and gene therapy.

*Inborn errors of immunity (IEI).* A group of genetic disorders that result in increased occurrence of infections, immunodysregulation (autoimmunity, autoinflammation and allergy) and cancer

*Leaky SCID.* A form of severe combined immunodeficiency (SCID), also known as atypical SCID, that presents with a small number of T cells, usually oligoclonal and with impaired function. These T cells may be autoreactive and produce inflammation in the skin, liver and lymphadenopathy, a condition known as Omenn syndrome.

*Jakinib.* A class of small molecules that inhibit JAK/STAT signal transduction pathways, with application in the management of allergic and inflammatory conditions. Also referred as Jak inhibitor.

*Massive parallel sequencing. (MPS),* A number of high throughput methods of DNA sequencing using simultaneous reactions in micro platforms. Also known as next-generation sequencing (NGS)

417

418 *Newborn screening.* Also known as Universal Newborn Screening (NBS), it is a public  
419 health program that identifies treatable disorders in newborns, mostly metabolic and  
420 hereditary. The goal of NBS is to diagnose and treat infants early to prevent or reduce  
421 severe medical outcomes.

422

423 *Non-coding region,* DNA sequences that do not code for a protein aminoacid sequence.  
424 Examples are introns and regulatory elements

425

426 *Precision medicine.* In IEI, refers to a medical approach of using therapeutic agents that  
427 address the specific molecular defect of the patient's condition.

428

429 *Somatic mosaicism.* The presence of a genetically distinct group of cells within tissues,  
430 secondary to a gene variant occurring after a fertilized oocyte starts dividing.

431

432 *Quality of Life.* A subjective measure of how a patient is doing at a particular point of  
433 time. It is multidimensional, including physical, mental, and social health. This  
434 information comes directly from the patient (patient-reported outcome), usually in the  
435 form of a questionnaire (patient's perception of their health). It aims to capture the well-  
436 being, whether of a population or individual, regarding both positive and negative  
437 elements within the entirety of their existence at a specific point in time.

438

439 *Whole exome sequencing.* A laboratory method aimed to sequence exons of all known  
440 genes, using massive parallel sequencing.

441

## METHODS

Systematic appraisal of the evidence and using Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) methodology<sup>5</sup> is internationally accepted as the optimal way to inform clinical decision making. While this Practice Parameter document does not formally employ all aspects of GRADE, we strive to adopt as many qualities as possible and present recommendations with a clear separation of strength of recommendation and Certainty of Evidence (informed by the formal GRADE domains) as possible.

The JTFPP conceived the project, obtained approvals from the parent organizations, recruited a workgroup of clinical experts and Chairs and provided overall oversight, including document review, feedback, and approval of the parameter. Within the membership of ACAAI and AAAAI, experts in the field of IEI were selected based on recent accomplishments, expertise, and leadership. The team reviewed the published scientific literature and provided concise summary recommendations. Workgroup discussions of recommendations were conducted twice a year. Simple vote and majority consensus were adopted to make decisions when differences of opinion occurred.

Recommendations are rated based on the strength of recommendation and the certainty of evidence. The paucity of controlled studies or trials combined with the relative rarity of some IEI presents a challenge for the GRADE system's use. Nonetheless, the statements have undergone extensive review by the authors, members of the JTF and the AAAAI, ACAAI and CIS, and given opportunities for all members to provide comments and feedback.

Each summary statement provides terms denoting the strength of recommendation and an assessment of the certainty of evidence following these definitions.

### Strength of Recommendation

<b>Strong = Recommended</b>
Desirable effects outweigh undesirable effects
Most patients would want this course of action
Most clinicians would implement these recommendations in patient care
Most policy makers would agree to follow these recommendations
<b>Conditional = Suggested</b>
Most patients would want this course of action, but many may not
Most clinicians would consider this course of action, but would review the case to see if other options are also appropriate and involve the patient in shared decision making
Policy makers will likely require additional information from many stakeholders

*Adapted from Chu DK<sup>5</sup>*

**Certainty of Evidence**

<b>High</b>	Further research is very unlikely to change the confidence in the recommendation.
<b>Moderate</b>	Further research is likely to affect the confidence of the balance of effects and may change the recommendation.
<b>Low</b>	Further research is likely to change the recommendation.
<b>Very Low</b>	The estimate of the effect is very uncertain.

*Adapted from Dykewicz M. et al.<sup>6</sup>*

## **EXECUTIVE SUMMARY**

Since the publication of the previous practice parameter in 2015, many advances in the care and diagnosis of patients with primary immune deficiency disorders (now also known as inborn errors of immunity (IEI)) have occurred. This practice parameter will discuss and highlight some of these changes, including the use of genetic testing in the diagnosis and in guiding treatment of IEI, newborn screening for severe T cell lymphopenia, and the use of targeted therapies and precision medicine, based on the identification of the immunopathology of the disorder. This practice parameter discusses groups of disorders based on the most recent disease classification system set out by the International Union of Immunology Societies (IUIS).<sup>7</sup>

Section and number	RECOMMENDATION	Strength	Certainty of Evidence
<b>SECTION 1: Clinical Approach to the Diagnosis Of IEI</b>			
1.1	<b>We recommend</b> investigating for IEI diagnosis in patients with recurrent, severe, or rare infections, autoinflammation, autoimmunity, severe atopy, atypical malignancy, bone marrow failure or combinations of these conditions.	Strong	High
1.2	<b>We recommend</b> obtaining a detailed family history to support the IEI diagnosis and to identify undiagnosed affected relatives.	Strong	Moderate
1.3	<b>We recommend</b> an integrated approach for the diagnosis of a suspected IEI: clinical, immunological and genetic components.	Strong	Moderate
1.4	<b>We recommend</b> that the evaluation of immunodeficiency should include testing for secondary causes of immunodeficiency.	Strong	Moderate
1.5	<b>We suggest</b> consultation with a clinical immunology expert and multidisciplinary care for the evaluation and follow up of suspected or diagnosed patients with IEI.	Conditional	Moderate
1.6	<b>We suggest</b> the provision of supportive resources (e.g., social, educational, emotional) for patients and families diagnosed with IEI.	Conditional	Low
<b>SECTION 2: Newborn screening for Severe Combined Immunodeficiency and Athymia- Diagnostic and Initial Approach</b>			
2.1	<b>We recommend</b> TREC quantitation for newborn population-based screening for the early identification of newborns with severe combined immunodeficiency (SCID) and complete athymia.	Strong	High

2.2	<b>We recommend</b> the urgent confirmation of an abnormal NBS for SCID with complete blood counts with differential and flow cytometric measurement of peripheral blood lymphocyte subset populations, including assessment of numbers of T, B and NK subsets and naïve T cells.	Strong	High
2.3	<b>We recommend</b> that diagnostic evaluation for SCID and athymia include genetic testing, ascertainment of maternal T cell engraftment, IgE levels, eosinophilia, T cell oligoclonality, T cell proliferation and adenosine deaminase enzyme activity.	Strong	High
2.4	<b>We recommend</b> urgent referral to centers with expertise in the care of severe immunodeficiency after SCID or athymia diagnosis is confirmed.	Strong	High
2.5	<b>We recommend</b> referral to clinicians with expertise in IEI for assessment and diagnosis of patients with non-SCID T cell lymphopenia detected by NBS.	Strong	Moderate
<b>SECTION 3 – Genetic Evaluation of IEI</b>			
3.1	<b>We recommend</b> single gene sequencing to test patients with suspected IEI who have a similarly affected family member with a known genetic defect or who present with a condition with a defect in a gene that might not be reliably analyzed using high-throughput massively parallel sequencing.	Strong	High
3.2	<b>We recommend</b> targeted gene panel sequencing including genes associated with IEI or exome sequencing as an initial step for genetic diagnosis, when a familial gene defect does not explain the patient's condition.	Strong	High
3.3	<b>We suggest</b> whole genome sequencing of individuals with suspected IEI and non-immunologic traits or with high suspicion for a non-coding genetic defect.	Conditional	Low

3.4	<b>We recommend</b> DNA copy number variant testing in patients with IEI with a suspected gene(s) deletion or duplication.	Strong	High
3.5	<b>We recommend</b> the American College of Medical Genetics and Genomics (ACMG) guidelines for evaluating gene variant pathogenicity.	Strong	High
3.6	<b>We recommend</b> familial genetic testing to aid in gene variant pathogenicity resolution.	Strong	High
3.7	<b>We suggest</b> familial genetic testing to ascertain risk of disease in currently unaffected relatives.	Conditional	Low
3.8	<b>We recommend</b> investigating multiple genetic diagnoses when a monogenetic diagnosis does not explain the patient's clinical characteristics.	Strong	Moderate
3.9	<b>We recommend</b> that genetic testing for patients with IEI can be ordered by clinicians with expertise in IEI and not limited to geneticists.	Strong	Moderate
<b>SECTION 4. Immunologic diagnosis of predominantly antibody deficiencies</b>			
4.1	<b>We recommend</b> that patients with suspected antibody deficiencies be evaluated with immunoglobulin measurement, antigen-specific antibody responses and lymphocyte phenotyping and exclusion of secondary causes of antibody deficiency.	Strong	High
4.2	<b>We recommend</b> the diagnosis of agammaglobulinemia for patients with low or undetectable serum immunoglobulin concentrations <b>and</b> low or undetectable circulating B lymphocytes <b>and</b> normal total CD3+ T cell numbers.	Strong	High
4.3	<b>We recommend</b> the diagnosis of CVID for patients with low serum IgG <b>and</b> low serum IgA and/or low IgM levels <b>and</b> demonstrated	Strong	High

	impaired antibody response to infection or immunization.		
4.4	<b>We recommend</b> the diagnosis of selective IgA deficiency (SIGAD) for patients older than 4 years of age with serum IgA below the limit of detection <b>and</b> normal serum IgG and IgM levels.	Strong	High
4.5	<b>We suggest</b> the diagnosis of IgG subclass deficiency for patients with recurrent infections <b>and</b> low levels of one or more serum IgG subclass levels (IgG1, IgG2 or IgG3 excluding IgG4) <b>and</b> normal serum total IgG levels.	Conditional	Moderate
4.6	<b>We suggest</b> the diagnosis of specific antibody deficiency (SAD) to polysaccharides for patients with recurrent respiratory infections <b>and</b> impaired antibody responses to polysaccharides <b>and</b> normal serum total IgG levels.	Conditional	Moderate
4.7	<b>We suggest</b> the diagnosis of specific antibody deficiency (SAD) to protein antigen for patients with recurrent infections <b>and</b> impaired antibody responses to protein antigen immunizations <b>and</b> normal serum total IgG levels.	Conditional	Low
4.8	<b>We recommend</b> that patients with low serum IgG and IgA levels <b>and</b> normal or elevated serum IgM level be given the diagnosis of immunoglobulin class-switch defects <b>after ruling out</b> combined immunodeficiencies that present with similar laboratory findings.	Strong	High
4.9	<b>We recommend</b> considering the diagnosis of transient hypogammaglobulinemia of infancy (THI), for infants and children with low serum IgG level <b>and</b> normal antibody response to immunizations <b>and</b> absent evidence of secondary causes.	Strong	High
4.10	<b>We suggest</b> considering the diagnosis of unspecified primary hypogammaglobulinemia for patients with significant morbidity from infections <b>and</b> low serum IgG level <b>and</b> normal cellular	Conditional	Moderate

	immunity AND absent evidence of secondary causes of low IgG levels <b>and</b> who do not fulfill diagnostic criteria for the above antibody deficiency disorders.		
<b>SECTION 5. Immunology Diagnosis of Combined Immunodeficiencies, Neutrophil Defects, Innate Immune Defects and Complement Deficiencies</b>			
<i>Combined immunodeficiencies less severe than SCID and syndromic immunodeficiencies</i>			
5.1	<b>We recommend</b> immunological investigations in patients with infectious manifestations, autoimmunity, malignancy, or organ-specific pathologies, suggesting cellular and humoral immunodeficiency.	Strong	High
5.2	<b>We recommend</b> the diagnosis of CID for patients with impairment (quantitative or functional) of both cellular and antibody immune functions.	Strong	High
5.3	<b>We recommend</b> immunological investigations and testing of diagnostic biological markers in patients with suspicion of CID <b>and</b> certain specific clinical findings in non-immunological organs and systems (syndromic features).	Strong	High
5.4	<b>We suggest</b> periodic assessments of immunological function in patients with CID and syndromic features.	Conditional	Low
<i>Neutrophil Defects</i>			
5.5	<b>We recommend</b> that patients with suspected quantitative neutrophil defects be screened with serial CBCs with differential.	Strong	High
5.6	<b>We recommend</b> that patients with suspected Leukocyte Adhesion Deficiency (LAD) be tested with flow cytometry analysis of relevant phagocyte surface molecules for LAD I and II, and targeted genetic testing for LAD I, II, III and IV.	Strong	High
5.7	<b>We recommend</b> that patients with suspected chronic granulomatous disease (CGD) have measurement of phagocyte	Strong	High

	oxidase activity <b>and</b> genetic testing for CGD associated gene defects.		
5.8	<b>We recommend</b> that patients with pulmonary alveolar proteinosis (PAP) be tested for pathogenic variants in the genes encoding the GM-CSF receptor and for autoantibodies to GM-CSF.	Strong	High
<i>Defects of Innate Immunity</i>			
5.9	<b>We recommend</b> that patients with suspected inherited susceptibility to a specific pathogen(s) be investigated for associated gene defects of innate immunity in addition to exclusion of adaptive immune defects and secondary causes of immune defects.	Strong	Moderate
<i>Defects of the Complement System</i>			
5.10	<b>We recommend</b> that patients with recurrent or severe infections by encapsulated bacteria <b>and</b> with normal antibody responses be evaluated for complement deficiency.	Strong	High
5.11	<b>We recommend</b> that patients presenting with thrombocytopenia, microangiopathic hemolytic anemia, <b>and</b> acute renal failure be screened for abnormalities of complement regulatory proteins and/or autoantibodies against complement Factor H (CFH) and related proteins 1 and 3 (CFHR1/CFHR3).	Strong	High
5.12	<b>We recommend</b> genetic testing when complement function screening is abnormal.	Strong	Moderate
<b>SECTION 6: Immunologic diagnosis of immune dysregulation disorders (PIRD) and autoinflammatory disorders</b>			
6.1	<b>We recommend</b> evaluation for IEL in patients with clinical manifestations of immune dysregulation, such as immunodeficiency, autoimmunity, lymphoproliferation and autoinflammation.	Strong	High

6.2	<b>We recommend</b> the assessment of cellular and humoral immunological functions in patients with suspected immune dysregulation disorders.	Strong	High
6.3	<b>We recommend</b> that patients with periodic fevers and chronic systemic inflammation should be evaluated for IEI and secondary causes such as infection, autoimmune disease, or malignancy.	Strong	High
6.4	<b>We recommend</b> that patients who exhibit lymphoproliferation and autoimmunity be evaluated for primary and secondary immune dysregulation syndromes.	Strong	High
<b>Section 7. Surveillance of potential clinical manifestations in IEI</b>			
7.1	<b>We suggest</b> the evaluation of growth (pediatrics) and nutritional status in patients with IEI.	Conditional	Moderate
7.2	<b>We suggest</b> testing for specific pathogen infections in patients with IEI known to be associated with high morbidity and mortality to these infections.	Conditional	Moderate
7.3	<b>We recommend</b> the assessment of complete blood cell counts with differential in patients with IEI.	Strong	High
7.4	<b>We recommend <i>against</i></b> routine screening for autoantibodies, given the high proportion of asymptomatic patients with autoantibodies in circulation.	Strong	Moderate
7.5	<b>We recommend</b> the evaluation for major organ system functions and screening for cancer and mental health disorders in patients with IEI.	Strong	High
<b>Section 8. Immunoglobulin Replacement</b>			
8.1	<b>We recommend</b> immunoglobulin replacement therapy for patients with IEI with IgG antibody deficiency.	Strong	High

8.2	<b>We recommend</b> that initial dosing of immunoglobulin for replacement therapy be at 400 mg/kg-600 mg/kg per month, followed by dose adjustment, if necessary	Strong	Moderate
8.3	<b>We recommend</b> the monitoring of serum IgG levels, complete blood cell counts, with differential and serum chemistry for patients on immunoglobulin replacement therapy.	Strong	Moderate
8.4	<b>We recommend</b> maintaining serum IgG levels at > 800 mg/dl to improve outcomes.	Strong	Moderate
8.5	<b>We recommend</b> that immunoglobulin replacement therapy is indicated as a continuous therapy for IEI.	Strong	Low
8.6	<b>We recommend</b> that a low or absent IgA, in the setting of low IgG levels, is not a contraindication for immunoglobulin replacement therapy.	Strong	Moderate
8.7	<b>We suggest</b> that the route of immunoglobulin replacement therapy be determined based on patient tolerance or preference.	Conditional	Moderate
<b>SECTION 9. Infection Prevention in IEI</b>			
9.1	<b>We recommend</b> targeted antimicrobial prophylaxis for patients with IEI and increased susceptibility to infections.	Strong	High
9.2	<b>We recommend</b> using only irradiated, cytomegalovirus (CMV)-negative, lymphocyte-depleted blood products for administration to patients with cellular or combined IEI.	Strong	Moderate
9.3	<b>We recommend</b> educating patients regarding environmental exposures that may increase the risk of infections for patients with IEI.	Strong	Moderate
9.4	<b>We suggest</b> prompt diagnostic testing in patients with IEI with acute infection symptoms and the use of antimicrobial regimens with duration longer than	Conditional	Low

	recommended for immunocompetent patients.		
<b>SECTION 10. Management of co-morbidities in IEI</b>			
10.1	<b>We suggest</b> that systemic comorbidities in patients with IEI should be evaluated and managed with a multidisciplinary team with expertise in IEI-related comorbidities.	Conditional	Moderate
10.2	<b>We recommend</b> prompt management of cytopenia(s) or malignancies in patients with IEI.	Strong	Moderate
<b>SECTION 11- Immunizations in the Management of IEI</b>			
11.1	<b>We recommend the</b> use of vaccine recommendations provided by local government agencies (e.g., CDC) for patients with IEI.	Strong	Low
<b>SECTION 12- Immune Reconstitution Therapy for IEI</b>			
12.1	<b>We suggest</b> that allogeneic HSCT for patients with IEI be performed at a center with experience in HSCT for IEI	Conditional	Moderate
12.2	<b>We recommend</b> that patients with typical SCID or leaky/atypical SCID receive definitive therapy with allogeneic HSCT or gene therapy.	Strong	High
12.3	<b>We recommend</b> that patients with congenital athymia disorders be treated with cultured thymus tissue implantation (CTTI).	Strong	High
12.4	<b>We recommend</b> that patients with CID disorders who have severe cellular immune defects or who manifest severe or refractory disease complications be considered for allogeneic HSCT.	Strong	Moderate
12.5	<b>We recommend</b> that patients with primary HLH disorders and patients with X-linked	Strong	High

	lymphoproliferative disease type 1 be evaluated for HSCT.		
12.6	<b>We suggest</b> that patients with immune dysregulation who manifest severe or refractory disease complications be evaluated for allogeneic HSCT.	Conditional	Moderate
12.7	<b>We recommend</b> HSCT for patients with defects in neutrophil number or function associated with severe clinical phenotypes.	Strong	High
12.8	<b>We suggest</b> HSCT in patients with innate immune defects affecting hematopoietic cell lineages and who manifest with recurrent, persistent severe infections.	Conditional	Moderate
12.9	<b>We recommend</b> that any patient with IEI who receives definitive treatment with HSCT, CTTI, or gene therapy receive life-long follow-up by clinicians experienced in evaluating immune reconstitution and monitoring for long-term complications of these procedures.	Strong	Moderate
<b>SECTION 13. Precision Medicine in IEI</b>			
13.1	<b>We recommend</b> the use of targeted therapies to treat IEI based on either an identified molecular defect or a clinical phenotype suggestive of a defective immune function.	Conditional to Strong	Low to High
<b>SECTION 14. Quality of Life in IEI</b>			
14.1	<b>We recommend</b> performing quality of life (QoL) measurements in patients with IEI, inclusive of patient reported outcome measurements (PRO) conducted with a validated tool.	Strong	Moderate
14.2	<b>We suggest</b> that patient reported outcomes (PROs) should be measured serially and at important management changes in the patient's clinical journey.	Conditional	Low

14.3	<b>We suggest</b> that patients with IEI have perceived health assessed at each clinical encounter.	Conditional	Low
14.4	<b>We suggest</b> that patients with IEI be assessed for fatigue at each clinical encounter.	Conditional	Low
14.5	<b>We suggest</b> implementing shared decision making between the provider and the patient as part of clinical care to improve QoL and patient satisfaction.	Conditional	Low

## **Section 1. Clinical Evaluation of IEI.**

**RECOMMENDATION 1.1. We recommend investigating for IEI diagnosis in patients with recurrent, severe, or rare infections, autoinflammation, autoimmunity, severe atopy, atypical malignancy, bone marrow failure or combinations of these conditions.**

**Strength of Recommendation – Strong**

**Certainty of Evidence – High**

Our understanding of the role of the immune system has broadened from defense of the host to include roles in inflammation, regeneration, metabolism, and development.

IEI are suspected in patients who have an unusual presentation of infections, which includes severe outcomes following infection, recurrence of infections, or infection with organisms that are deemed opportunistic (i.e., do not occur in any significant frequency in those with normal immunity).<sup>8</sup> IEI are considered in patients who have atypical presentations of autoimmune diseases, which includes onset at early age, severe manifestations, multiple autoimmune diseases, and those refractory to treatment.<sup>8-10</sup> IEI are also considered in patients with chronic inflammatory processes, which includes autoinflammation, granulomas, severe or prolonged inflammation after infection, or tissue injury.<sup>11, 12</sup> IEI may be diagnosed in patients with very-early onset inflammatory bowel disease, especially under age 6 years.<sup>13, 14</sup> IEI may be considered in patients with severe atopy, with unusual chronicity or refractory to treatment.<sup>15, 16</sup> **Sections 2, 3, 4, 5 and 6** of the Practice Parameter provide guidelines for the diagnostic approach for specific IEI.

IEI are classified according to the principal immunologic mechanisms that are disrupted or dysregulated. Nine broad categories are updated by the International Union of Immunological Societies (IUIS) every 2 years.<sup>7, 17</sup> IEI are presented in tables with associated defective genes and the reported clinical and immunological characteristics. **(Table 1.1)** Disorders affecting T cell function are in IUIS Tables I and II **(see Section 2**

**and 5.1)** Primary antibody disorders are classified in IUIS Table III (**see Section 4**). Immunodysregulation disorders, characterized by autoimmunity and inflammation, with and without susceptibility to infections, are included in IUIS Table IV (**see Section 6**). Primary neutrophil disorders are in IUIS Table V (**see Section 5.2**), while complement deficiencies are in IUIS Table VIII (**see Section 5.4**). IUIS Table VI groups innate immunity defects conferring high risk of infection by specific microorganisms. (**see Section 5.3**). Autoinflammatory disorders related and not related to inflammasome dysfunction are classified in IUIS Table VII (**see Section 6**). The IUIS Table IX lists primary bone marrow failure conditions, which may manifest with increased frequency of infections and are commonly managed by hematology/oncology specialists. The IUIS classification includes Table X to compile phenocopies of inborn errors of immunity for clinician awareness and to be considered when a genetic diagnostic is uncertain. These conditions have clinical presentations similar (phenocopies) to IEI and are caused by an acquired disease process, such as the development of neutralizing anti-cytokine antibodies or somatic pathogenic gene variants. Table IX and X disorders are not addressed in detail in this practice parameter.

**Table 1.1. IUIS Classification of Human Inborn Errors of Immunity 2024**

<b>Table I</b>	Immunodeficiencies affecting cellular and humoral immunity 1. T-B+ Severe combined immunodeficiencies (SCID) 2. T-B- SCID 3. Combined immunodeficiencies. Generally less profound than SCID.
<b>Table II</b>	Combined immunodeficiencies with associated or syndromic features 1. Immunodeficiency with Congenital thrombocytopenia 2. DNA repair defects 3. Thymic Defects with additional congenital anomalies 4. ImmunoOsseus Dysplasias 5. Hyper IgE syndromes 6. Defects of vitamin B12 and folate metabolism 7. Anhydrotic ectodermal dysplasia with immunodeficiency 8. Calcium channel defects 9. Other
<b>Table III</b>	Predominantly antibody deficiencies 1. Severe reduction of all serum immunoglobulins with profoundly decreased B cell numbers. 2. Severe reduction of at least 2 serum immunoglobulin isotypes with normal or low B cell numbers, CVID. 3. Severe reduction in serum IgG and IgA with normal/elevated IgM and normal B cell numbers, hyper IgM.

	4. Isotype, light chain or functional deficiencies with generally normal B cell numbers
<b>Table IV</b>	Diseases of immune dysregulation <ol style="list-style-type: none"> <li>1. Familial Hemophagocytic lymphohistiocytosis (FHLH).</li> <li>2. FHLH syndromes with hypopigmentation.</li> <li>3. Regulatory T cell defects.</li> <li>4. Autoimmunity with or without lymphoproliferation.</li> <li>5. Immune dysregulation with colitis.</li> <li>6. Autoimmune lymphoproliferative syndrome.</li> <li>7. Susceptibility to EBV and lymphoproliferative conditions</li> </ol>
<b>Table V</b>	Congenital defects of phagocyte number or function <ol style="list-style-type: none"> <li>1. Congenital neutropenia.</li> <li>2. Defects of motility.</li> <li>3. Defects of respiratory burst.</li> <li>4. Other non-lymphoid defects.</li> </ol>
<b>Table VI</b>	Defects in intrinsic and innate immunity <ol style="list-style-type: none"> <li>1. Mendelian Susceptibility to Mycobacterial Disease (MSMD)</li> <li>2. Epidermodysplasia verruciformis (HPV)</li> <li>3. Predisposition to severe viral infections</li> <li>4. Herpes Simplex encephalitis</li> <li>5. Predisposition to invasive fungal disease</li> <li>6. Predisposition to mucocutaneous candidiasis</li> <li>7. TLR signaling pathway deficiency</li> <li>8. Other IEI related to non-hematopoietic tissues</li> <li>9. Other IEI related to leukocytes</li> </ol>
<b>Table VII</b>	Autoinflammatory disorders <ol style="list-style-type: none"> <li>1. Type I interferonopathies.</li> <li>2. Defects affecting the inflammasome.</li> <li>3. Non-inflammasome related conditions.</li> </ol>
<b>Table VIII</b>	Complement deficiencies
<b>Table IX</b>	Bone marrow failures
<b>Table X</b>	<i>Phenocopies of inborn errors of immunity.</i>

536

537 **RECOMMENDATION 1.2. We recommend obtaining a detailed family history to**  
538 **support the IEI diagnosis and to identify undiagnosed affected relatives.**

Strength of recommendation - **Strong**

Certainty of evidence – **Moderate**

A family history that reveals manifestations of IEI and high frequency of infections as compared to other household members is suggestive of an IEI. Beyond infections, family history should inquire the presence of autoimmunity, inflammatory features (e.g., vasculitis, colitis, fevers, rashes), cancers, and severe atopy. A detailed family history might identify relatives that are also affected by the patient's condition. Around 1.5% of patients in a large cohort of patients with IEI were diagnosed because of a family history,<sup>8</sup> while another reports 26% having positive family history at initial presentation.<sup>18</sup>

Because IEI are genetic disorders, a detailed understanding of the family history, including consanguinity, can suggest potential patterns of inheritance (e.g., autosomal dominant, X-linked). The inheritance pattern of symptoms could be useful for defining the pathogenicity of identified gene variants. Furthermore, an awareness of inheritance patterns guides genetic counseling regarding the probability of disease in future descendants.

**RECOMMENDATION 1.3. We recommend an integrated approach for the diagnosis of a suspected IEI: clinical, immunological, and genetic components.**

Strength of recommendation- **Strong**

Certainty of evidence - **Moderate**

The evaluation for the diagnosis of suspected IEIs requires a synthesis of three important components:<sup>19, 20</sup> 1) clinical findings obtained from history and physical exam; 2) supporting immunological findings obtained from laboratory studies; and 3) genetic findings. Screening with a detailed history is necessary, eliciting frequency and severity of infections, autoimmunity, episodes of fever or inflammation, malignancy, and severe atopy.<sup>17</sup> As discussed in **RECOMMENDATION 1.2**, the family history is often helpful.<sup>18</sup> Physical exam should focus on features of syndromes with characteristic dysmorphisms (e.g., face features in DiGeorge syndrome), stigmata of recurrent infections (e.g., warts, bronchiectasis), autoimmunity (e.g., alopecia, vitiligo), lymphoproliferative phenotypes (e.g., lymphadenopathy, splenomegaly), and severe atopy (e.g., generalized lichenified and infected eczema). Based on clinical findings, immunological tests should focus on assessing parameters of the molecular and cellular pathways most likely to be implicated in the suspected clinical syndrome.<sup>21</sup> For example, disseminated warts prompt an evaluation of T cells and NK cells. The IUIS phenotypical classification tables are useful to guide diagnostic investigations.<sup>17</sup> Because IEI might present with atypical manifestations or an incomplete clinical picture, genetic testing is recommended from the start of the workup – details of specific diagnostic tests to order are covered in other Sections. (**Sections 2-7**).

**RECOMMENDATION 1.4. We recommend that the evaluation of immunodeficiency should include testing for secondary causes of immunodeficiency.**

Strength of recommendation – **Strong**

Certainty of evidence- **Moderate**

In patients where susceptibility to infection is among the chief concerns, a broader consideration should be given to secondary immunodeficiencies, (**Table 1.2**) which are more prevalent as a group than IEI, particularly in adult patients.<sup>22, 23</sup> There are microscopic or macroscopic anatomic causes of recurrent infections. For example, structural and functional defects of the respiratory epithelial cilia increase the risk of recurrent pneumonias, as observed in cystic fibrosis, primary ciliary dyskinesia, or from chemical damage due to second-hand smoke.<sup>24</sup> Macroscopic anatomic defects of the nose and paranasal sinuses and adenoidal hypertrophy can mechanically block mucus flow and drainage, favoring infection. Allergic mucosal inflammation also reduces pathogen clearance.<sup>24</sup> Infectious diseases that target the immune system (such as human immunodeficiency virus (HIV) infection) lead to a deficient immune response.

Secondary immunodeficiency conditions arise with the use of immunosuppressive medications in autoimmunity and blood cancers. A few medications can impair immune cells in a non-predictable manner, such as anti-epileptic drugs.<sup>25, 26</sup>

Disorders where immune cells and immunoglobulins are lost from the gut, respiratory tract, or lymphatic vessels such as hydrops, protein-losing enteropathy, intestinal lymphangiectasis, lympho-venous malformations, and chylothorax. also result in immunodeficiency,

Some extremes of physiological states can result in immune deficiency or dysregulation, including malnutrition, extreme heat or cold, and sleep deprivation. Aging individuals may develop immune defects that predispose them to infections.<sup>27, 28</sup> Neonates also have immune impairment of both innate and adaptive immunity compared to older children, which increase their risk for infections and are exacerbated by premature birth.<sup>29-31</sup>

The presence of autoantibodies against cytokines can result in clinical phenocopies of IEI with infection susceptibility and autoimmunity.<sup>32-34</sup> Thymus malignancies and some IEI are associated with development of elevated levels of autoantibodies to cytokines, including RAG1/2 deficiency, IPEX, AIRE deficiency, NFKB2 deficiency, and NEMO deficiency.<sup>34, 35</sup>

**Table.1.2. Examples of secondary causes of immunodeficiency:**

-	Anatomical: nasal polyposis, deviated septum, adenoidal hypertrophy.
---	--

-	Defective epithelial barriers: primary ciliary dyskinesia, cystic fibrosis.
-	Malnutrition.
-	Infections targeting immune cells: HIV infection, measles, EBV infection.
-	Use of immunosuppressive medication: corticosteroids, cyclosporine, rituximab
-	Lymphatic system malformations
-	Prematurity and advanced age

\*HIV, human immunodeficiency virus; EBV, Epstein-Barr virus.

**RECOMMENDATION 1.5. We suggest consultation with a clinical immunology expert and multidisciplinary care for the evaluation and follow up of suspected or diagnosed patients with IEI.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Moderate**

Primary care physicians and other health care professionals conduct screening evaluations for IEI.<sup>36-38</sup> However, consultation with a clinical immunology expert is recommended to confirm IEI diagnosis, interpretation of abnormal test results and management.<sup>39</sup> For patients with established IEI diagnoses, evaluations should be conducted regularly (every 4 to 12 months, depending on the diagnosis) by a health care professional with training and experience in the care of patients with IEI (**see Section 7**).

The multisystem nature of IEI necessitates an integrated multidisciplinary approach to management. This approach provides significant cost savings, improved quality of life, and improved outcomes.<sup>40-42</sup> Such an approach optimizes medical treatments and permits integration of health and social care professionals and physical and occupational therapy into the patient's overall care. Different patient comorbidities require the involvement of different clinical teams. For example, early onset inflammatory bowel disease clinics may require a clinical immunologist and a gastroenterologist, as well as pharmacists and geneticists.<sup>43</sup> Within the same concept, a clinic focusing on patients with 22q11 deletion syndrome additionally requires experts in otorhinolaryngology, endocrinology, cardiology, and speech therapy.<sup>44</sup>

**RECOMMENDATION 1.6: We suggest the provision of support resources (e.g., educational, emotional) for patients and families diagnosed with IEI.**

Strength of recommendation - **Conditional**

Certainty of evidence- **Low**

IEI are considered rare conditions and are unfamiliar to most people. Thus, when faced with an IEI diagnosis, most patients do not have familial or cultural examples to help guide their understanding of disease process and management. Patients and families need to be given sufficient educational material in the appropriate language and level of detail so that they understand the inheritance, causes, manifestations, and natural histories of their IEI.<sup>45</sup>

Receiving an IEI diagnosis can be distressing and may elicit depression in adult patients<sup>46, 47</sup> and in parents of children with IEI.<sup>48</sup> When the IEI diagnosis is made in the neonatal period, there is added risk of postpartum depression. Screening for depression in patients and their immediate relatives might be considered.<sup>49-51</sup>

Patient-based organizations are additional resources for advocacy and support from other patients and families, education regarding new developments and treatments, and government or private support of research programs. Patients and families may establish long-term relationships with health care professionals, including physicians, nurses, and social workers to help obtain the best outcomes for their diseases.

## **SECTION 2. Newborn Screening (NBS) for severe combined immunodeficiency and athymia- diagnosis and initial approach.**

Infants born with severe combined immunodeficiency (SCID) or with congenital athymia have absent or very few naïve T cells in their blood. This deficiency can be quantitatively detected via PCR amplification of T cell receptor excision circles (TRECs), a byproduct of T cell receptor rearrangement, which occurs in the thymus during T cell maturation. NBS for SCID allows early diagnosis and treatment of SCID and congenital athymia.<sup>52</sup>

SCID meets the key criteria for NBS as a public health initiative: (1) absence of TRECs constitutes a reliable biomarker to identify asymptomatic infants with SCID and athymia, (2) use of NBS decreases morbidity and mortality, and (3) effective therapies are available, in the form of hematopoietic stem cell transplantation (HSCT) and gene therapy.

### **RECOMMENDATION 2.1: We recommend TREC quantitation for newborn population-based screening for the early identification of newborns with severe combined immunodeficiency (SCID) and complete athymia.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

In the United States, initial pilot programs in Massachusetts, Wisconsin and the Navajo Nation using TREC-based screening for SCID started in 2008.<sup>53</sup> Early identification of

SCID-affected infants in these groups, as well as cost effectiveness modelling,<sup>54-56</sup> led to the addition of SCID to the Department of Human Health Services Recommended Uniform Screening Panel (RUSP) in 2010. By 2018, all 50 US states had adopted TREC-based NBS for SCID (SCID NBS).<sup>57</sup> SCID NBS allowed the determination of the SCID incidence in the US population to be 1/65,000 live births, higher than previous estimates.<sup>58</sup> Nearly all infants are diagnosed with SCID in the US through SCID NBS.<sup>59</sup> Importantly, post-transplant survival has improved with the implementation of SCID NBS.<sup>60</sup> Harmonization of interpretation of TREC results, including consensus language to describe abnormal results and urgent results for all US States is being pursued.<sup>61</sup>

SCID NBS via the TREC assay identifies typical SCID, almost all cases of atypical and leaky SCID (including Omenn Syndrome), and congenital athymia as the primary targets of screening.<sup>58, 62-64</sup> Moreover, a proportion of cases with combined immunodeficiency (CID) and syndromic immunodeficiency also have abnormal SCID NBS if total naïve T cell numbers are low; such disorders include ataxia telangiectasia, 22q11 deletion syndrome without complete athymia and others.<sup>58, 64, 65</sup> Patients with these conditions exhibit widely variable T cell lymphopenia and are not uniformly detected by SCID NBS. Certain severe cellular immune deficiencies (such as MHC Class II) or, rarely, pathogenic variants causing late-onset SCID, (such as hypomorphic adenosine deaminase (ADA) defects), are not detected via SCID NBS.<sup>66, 67</sup> Therefore, if concern arises for an immune disorder based on history or clinical presentation, diagnostic testing should be pursued, despite normal SCID NBS.

In the case of SCID due to ADA deficiency, concomitant use of tandem mass spectrometry may improve upon detection provided by TREC alone.<sup>68</sup> The use of kappa light chain receptor excision circle (KREC) quantitation for B cell deficiency may be adopted by NBS programs to identify additional patients with IEI.<sup>69</sup> Genetic sequencing to detect other IEI is being evaluated for NBS.<sup>70</sup> Population-based genome sequencing programs for treatable IEI could be both comprehensive and cost effective.<sup>71, 72</sup>

**RECOMMENDATION 2.2: We recommend the urgent confirmation of an abnormal NBS for SCID with complete blood counts with differential and flow cytometric measurement of peripheral blood lymphocyte subset populations, including assessment of numbers of T, B and NK subsets and naïve T cells.**

Strength of recommendation: **Strong**

Certainty of evidence **High**.

Approximately 1/15,000 live births in the US are born with clinically significant lymphopenia.<sup>73</sup> While SCID NBS is highly sensitive to screen for the primary targets of SCID and complete athymia, it is not a diagnostic test. Indeed, only about 15% of patients with a positive SCID NBS are ultimately diagnosed with SCID, while others have secondary causes of T cell lymphopenia (e.g., prematurity) or have normal

lymphocyte populations.<sup>58, 73</sup> Therefore, it is important for newborn screening programs to collaborate with clinical immunology experts to ensure prompt confirmatory testing, which includes enumeration of absolute counts of T cell subsets (CD3, CD4, CD8), naïve CD4 T cells (defined by CD45RA expression alone or in conjunction with other markers, such as CCR7 and CD62L) or CD4+ recent thymic emigrants (CD4 RTE, as identified by expression of CD31, CD45RA and CD4).<sup>74, 75</sup>

Unless the above laboratory tests are sufficient to rule out SCID or a T cell lymphopenia disorder, infants require a complete birth history, family history and physical exam by a physician with expertise in pediatric immunology. A diagnosis of SCID or congenital athymia should be suspected if the Primary Immune Deficiency Treatment Consortium (PIDTC) criteria for SCID diagnosis are met (**See Table 2.1**).<sup>76</sup> The threshold for clinically significant T cell lymphopenia may vary, but in general, lower than 1,000 cells/uL with lower than 20% of naïve CD4 T cells suggests an increased risk for infection for newborns. Other concerning features are low B cell or NK cell counts, dysmorphisms associated with immunodeficiency, and family history of T cell deficiency. While patients with an abnormal SCID NBS but normal clinical and laboratory evaluation can be discharged from immunologic care, it is recommended for these infants to be reassessed within 3 to 6 months.<sup>74, 77</sup>

Prematurity and low birth weight can be associated with T cell lymphopenia that improves with age and weight gain.<sup>78</sup> However, 10% of infants with SCID are premature and/or have low birthweight; therefore, it is recommended to maintain a high level of suspicion for SCID in premature infants with an abnormal SCID NBS and abnormal T cell counts.<sup>79</sup> Other causes of abnormal SCID NBS are due to maternal conditions during pregnancy, such as the use of immunosuppressive therapies (e.g., azathioprine) and diabetes mellitus.<sup>80</sup>

**Table 2.1: PIDTC 2022 Definitions for SCID<sup>76</sup>**

SCID subtype	Criterion 1	Criterion 2	Criterion 3	Criterion 4
<b>Typical SCID</b> Criteria 1 & 2 OR criteria 1 & 3 OR criteria 4	Very low T cells ( $<0.05 \times 10^3/L$ )	Pathogenic variant in SCID-associated gene	No alternate explanation for low T cell count AND, EITHER: Undetectable or low TREC OR $<20\%$ naïve CD4 T cells	Presence of maternal T cells engraftment
<b>Leaky/atypical SCID</b> Criteria 1 & 2 & 4 OR criteria 1 & 3 & 4	<u>Two or more of:</u> -Low T cell number for age -Oligoclonal T cells	Pathogenic variant in SCID-associated gene	Reduced T cell proliferation	<u>Does not have:</u> -Other SCID subtype -CID with known phenotype -Thymic disorder -Other disorder with low T cell number

	-Abnormal TREC OR <20% naïve CD4 T cells			
<b>Omenn syndrome</b> All 4 criteria	>80% of CD4 T cells have CD45RO memory phenotype	Pathogenic variant in SCID-associated gene	Generalized rash AND absence of maternal T cell engraftment	<u>Two or more of:</u> -Eosinophilia -Elevated IgE -Abnormal TREC - Lymphadenopathy -Hepatomegaly and/or splenomegaly -Oligoclonal T cells

**RECOMMENDATION 2.3: We recommend that diagnostic evaluation for SCID and athymia include genetic testing, ascertainment of maternal T cell engraftment, IgE levels, eosinophilia, T cell oligoclonality, T cell proliferation and adenosine deaminase enzyme activity.**

Strength of recommendation: **Strong**

Certainty of evidence **High**.

Once SCID or athymia is suspected, urgent follow up testing is needed to confirm a diagnosis and optimize management. Diagnostic criteria for typical SCID, leaky/atypical SCID and Omenn syndrome were updated in 2022 by the PIDTC based on review of clinical presentation of 379 infants with SCID (**Table 2.1**).<sup>76</sup> Omenn syndrome presents with eosinophilia and elevated serum IgE level. Choice of immune reconstitution treatment is influenced by specific genotypes, some of which are associated with radiosensitivity, and the presence of oligoclonal T cells (**see Section 12**). Assessment of T cell oligoclonality by evaluating the T cell receptor repertoire diversity is available in immunology laboratories. Transplacental maternal T cell engraftment can be tested in patients with T cell counts > 50 cell/uL, by comparing HLA markers expressed in T cells and non-T cells (e.g., neutrophils). In cases where adenosine deaminase deficiency is suspected (i.e., patients with very low numbers of T and B cells), measuring adenosine deaminase enzyme activity is indicated.<sup>81</sup>

**RECOMMENDATION 2.4: We recommend urgent referral to centers with expertise in the care of severe immunodeficiency after a SCID or athymia diagnosis is confirmed.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Infants with SCID and complete athymia are at high risk for the development of infection and other life-threatening complications.<sup>77</sup> The implementation of SCID NBS has

resulted in improved survival and clinical outcomes, due to early diagnosis and management, decreasing the risk of infections, organ damage, and increasing survival.<sup>60, 82, 83</sup> Therefore, urgent follow-up with a clinician with expertise in the evaluation and management of infants with SCID or athymia is important to achieve the best outcomes for these complex patients.<sup>84</sup> Measures to reduce morbidity and mortality due to CMV infection are recommended.<sup>85, 86</sup> Live vaccines should be avoided.<sup>87, 88</sup> **Table 2.2** summarizes recommendations for surveillance of infections and antibiotic prophylaxis in patients with SCID. (**Also see Sections 8-11**)

**Table 2.2. Recommendations for the care of infants with SCID diagnosis (\*)**

Recommendation	Frequency	Comment
Test CMV PCR in urine and in blood	Baseline and every 3 to 4 months	If present, treat CMV infection (Valganciclovir, 16 mg/Kg/dose, orally twice a day or Ganciclovir, 6 mg/kg/dose, intravenously twice a day). Alternatives are cidofovir and foscarnet.
Test serum anti-CMV IgG in patient's mother	Baseline	If suspected or confirmed maternal CMV infection, avoid breastfeeding
Test EBV PCR in blood	Baseline and every 3 to 4 months	If present, treat EBV infection (valganciclovir or ganciclovir, dose similar to EBV).
Test HIV PCR or antigen tests in blood	Baseline	Treat HIV infection
Test PCR-based respiratory viral pathogen panel (e.g., Influenza A and B, Parainfluenza 1, 2 and 3, adenovirus, rhinovirus, human metapneumovirus).	When there is an increase of nasal secretions or respiratory symptoms such as cough and shortness of breath	Treat respiratory viral infection: oxygen support, beta-agonists, antiviral drugs (e.g., Oseltamivir) if indicated.
Environment with reduced exposure to infections	At all times	Inpatient (with reverse isolation) or outpatient (close distance to a medical center)
Prophylaxis for PJP	Daily, starting at one month of age	Trimetoprim/sulfamethoxazole 2.5 mg (of trimethoprim component)/Kg/day

Prophylaxis for Candidiasis	Daily	Fluconazole 3 mg/Kg/day oral
Prophylaxis for herpes infection	Daily	Acyclovir 12.5 mg/kg/day oral
Prophylaxis for RSV infection	Monthly during RSV season	palivizumab or nirsevimab-alip
Immunoglobulin replacement therapy	Monthly or weekly	Intravenous or subcutaneous routes (400 mg/Kg/month)
Avoid live viral vaccines		Includes: rotavirus, MMR, BCG, oral polio. Household members are encouraged to receive all scheduled vaccines

CMV, cytomegalovirus; EBV, Epstein-Barr virus; HIV, human immunodeficiency virus; PJP, Pneumocystis jiroveci pneumonia; RSV, respiratory syncytial virus

(\*) From Dorsey MJ, et al.<sup>77</sup>

**RECOMMENDATION 2.5: We recommend referral to clinicians with expertise in IEI for assessment and diagnosis of patients with non-SCID T cell lymphopenia detected by NBS.**

Strength of recommendation: **Strong**

Certainty of evidence **Moderate**

Infants with non-SCID T cell lymphopenia should be monitored longitudinally.<sup>74, 78</sup> These infants may be immunologically defined by having CD3+ T cell count >50 but <1,000 cells/uL, with naïve CD4+ T cells comprising most of the population and without maternal T cell engraftment or Omenn syndrome. Once these criteria are met, clinical history should carefully assess for evidence of secondary loss of T cells (e.g., chylous loss), prematurity and/or dysmorphic features consistent with other syndromic conditions (e.g., chromosome 22q11.2 deletion syndrome).<sup>74, 78</sup>

Diagnostic testing in this setting includes quantitative assessment of serum levels of IgG, IgA, IgM and IgE; and genetic testing, including for 22q11.2 deletion syndrome (**see Section 3**). Inactivated vaccines of the routine primary series should be administered, and antibody responses to these immunizations be monitored to assess overall immune function.

We suggest the following schedule for ongoing immunologic evaluation and monitoring based on reported trajectories for resolution of non-SCID T cell lymphopenia<sup>74, 78, 89</sup>

**(See Section 4 and 5):**

- At 3 months of age: reassess lymphocyte subsets including naïve T cell populations, IgG, IgA, IgM, IgE levels, genetic testing for ICI for lymphopenia that is unexplained and persistent.
- At 6-7 months of age: reassess lymphocyte subsets including naïve T cell populations, T cell proliferation responses, IgG, IgA, IgM, IgE levels, response to inactivated vaccines if not started on immunoglobulin replacement.
- Continue clinical and immunological reassessment every 3 to 6 months. May increase time between evaluations if immuno competence is achieved.

### **SECTION 3 - Genetic Evaluation of ICI**

Determination of an underlying genetic diagnosis assists in the evaluation and treatment of patients with suspected ICI.<sup>90</sup> ICI are caused by defects in over 505 genes, underscoring the need for genetic evaluation.<sup>7</sup> The application of massively parallel sequencing (MPS) for genetic testing (e.g. exome sequencing) and decreasing costs have contributed to the availability of genetic tests in clinical settings. Genetic testing has led to the broadening of clinical phenotypes (e.g., very early onset inflammatory bowel disease as a manifestation of chronic granulomatous disease) and selection of targeted therapies based on the identified disease mechanism (e.g., JAK inhibition for *STAT1* or *STAT3* gain of function). A variety of testing methods are available (**Table 3.1**), and depending on the question being pursued, some are preferred over others.

Genetic counseling before and after genetic testing is recommended and includes the nature of gene defects, inheritance patterns, disease penetrance and implications for family planning.

This can be performed by a genetic counselor or an immunologist with expertise in ICI. Informed consent for genetic testing is required, because of the potential impact of the results on the patient's health, family relationships and future decisions. Patients need to understand the limitations of genetic testing and every effort should be made to address psychological distress associated with genetic diagnoses. Sensitive genetic information should be protected from unauthorized disclosure.

**Table 3.1. Detection capabilities of genetic testing platforms for various genomic findings**

Genetic defect	Sanger sequencing	ICI targeted gene panel sequencing	Exome sequencing	Whole genome sequencing	Chromosomal microarray analysis
----------------	-------------------	------------------------------------	------------------	-------------------------	---------------------------------

Coding SNV	YES(a)	YES	YES	YES	No
Non-coding SNV	YES(a)	YES(b)	YES(b)	YES	No
CNV	No	YES(b)	YES(b)	YES	YES(b)
Mosaicism	YES	YES	YES(b)	YES(b)	No
High genomic homology	YES	No	No	YES	No
Non-IEI gene defects	No	No	YES	YES	YES

SNV, single nucleotide variant; CNV, copy number variation. (a) if SNV is known. (b) sensitivity varies with test protocol design

**RECOMMENDATION 3.1: We recommend single gene sequencing to test patients with suspected IEI who have a similarly affected family member with a known genetic defect or who present with a condition due to a defect in a gene that might not be reliably analyzed using high-throughput massively parallel sequencing.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Single gene sequencing, also known as Sanger sequencing, is based on polymerase chain reaction (PCR) amplification.<sup>91</sup> Another approach is the use of MPS-based test focused entirely on one large gene or a gene for which high read-depth sequence coverage is needed. (**See RECOMMENDATION 3.2 and 3.3**). A strength of Sanger sequencing is its high accuracy and has been considered the gold standard for gene testing. This method was used to confirm gene variants identified by MPS-based tests. However, with MPS accuracy improving and approaching that of Sanger sequencing over time,<sup>92</sup> this practice is becoming unnecessary,<sup>93-96</sup> with exception of genes for which MPS-based tests have difficulty producing high-quality data.<sup>96</sup> Examples include genes with pseudogenes or repetitive regions and genes with established pathogenic variants in non-coding regions, intronic or untranslated regions (UTRs). Sanger sequencing may distinguish genes from pseudogenes, which are non-functional genetic segments that evolutionarily arose from duplication of existing genes. Genes linked to known IEI that have pseudogenes include *IKBKG* (encoding the NEMO protein), *NCF1* (encoding the p47phox protein), *ATAD3A*, *C4A*, *CFB*, *IRAK1*, *SBDS*, and *USP18*.<sup>97</sup>

Single gene sequencing is indicated when IEI is suspected in a patient for whom a specific gene variant is known to be responsible for the same IEI in one or more direct

relatives of the patient. Single gene sequencing can also be used to establish carrier status for apparently unaffected family members (**see RECOMMENDATION 3.6**).

Single gene sequencing should not be used when multiple candidate genes are associated with the clinical presentation (notably, almost all IEI fall into this situation). Single gene sequencing cannot detect copy number or structural variants.

Single gene sequencing has been used if somatic mosaicism is suspected. Somatic mosaicism is a term to describe the presence of more than one genetically defined cell populations in one individual. For example, somatic mosaicism has been reported in patients with variants in genes such as *FAS*<sup>98</sup> and *NLRP3*<sup>99</sup> (**Table 3.2**). While Sanger sequencing samples of different tissues or cells has been used to evaluate mosaicism, it is not sensitive below a threshold of 15%–20%.<sup>100</sup> In contrast, MPS-based tests with very high read depth can detect variant allele frequencies below 1% in one sample.<sup>101</sup>

**Table 3.2: Examples of IEI genes associated with mosaicism**

<i>CYBB</i>	<i>KRAS</i>	<i>NLRC4</i>	<i>TNFRSF1A</i>
<i>FAS</i>	<i>NOD2</i>	<i>PIK3R1</i>	<i>TMEM173</i>
<i>IL6ST</i>	<i>NRAS</i>	<i>STAT3</i>	<i>TLR8</i>
<i>JAK1</i>	<i>NLRP3</i>	<i>STAT5B</i>	<i>UBA1</i>

**RECOMMENDATION 3.2: We recommend targeted gene panel sequencing including genes associated with IEI or exome sequencing as an initial step for genetic diagnosis, when a familial gene defect does not explain the patient's condition.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Because exome sequencing and comprehensive IEI gene targeted panel sequencing are similar in diagnostic yield for detecting pathogenic gene variants,<sup>102</sup> the choice between these two test methods is based on availability, turnaround time, sequencing depth, copy number variation (CNV) reporting, and cost. These factors will be specific for the clinical needs of each patient.

Exome sequencing aims to sequence all coding regions within the genome. In contrast, targeted gene panels evaluate coding and selected non-coding regions of a selected group of genes associated with a particular patient phenotype. The number of genes in these panels can vary from relatively few (e.g., a SCID panel may analyze 24 genes), to panels of over 500 genes that encompass the most known IEI as well as additional genes for which defects may mimic IEI.<sup>102-104</sup> Both targeted gene panels and exome sequencing use a library of DNA or RNA capture probes, which hybridize with complementary target sequences to allow for isolation of the specific regions of genomic

DNA. Targeted gene panels may include PCR based amplicons for sequencing. In addition to the coding regions, the immediately adjacent intronic regions are sequenced to account for variants that impact splicing. Some targeted panels capture non-coding regions known to harbor pathogenic variants of certain genes (e.g., *GATA2*). Of note, some targeted gene panels use exome sequencing capture probes and limit the analysis and reporting to disease-associated genes. Such panels are also called “focused exome sequencing,” “exome slicing,” or “virtual gene panels.”<sup>102-104</sup>

DNA is sequenced using MPS high-throughput technologies. Sequencing data are then aligned to a reference genome, and variants are identified and annotated. The depth of coverage (the number of unique sequencing reads per nucleotide in the reconstructed sequence) will vary based on the technology used. Average read depth for a targeted gene panel may be 500x or higher, while the average read depth for exome sequencing is typically around 100x.<sup>102-104</sup> These technologies are limited in their ability to analyze genes associated when pseudogenes are present.

Targeted gene panel sequencing is expected to have the lowest cost and fastest turnaround time among MPS-based tests because of the small number of gene variants that are identified and annotated. Additionally, the increased depth of coverage obtained with targeted gene panels allows for detection of somatic variants with low allele frequencies.<sup>102-104</sup>

For CNV detection, targeted gene panels exhibit higher sensitivity and reliability than exome sequencing tests due to the higher read-depth provided in panel tests.<sup>105-107</sup>

Small CNVs may not be identified (**see RECOMMENDATION 3.4**). Because many computational tools are newly developed and require validation for clinical reporting, CNV detection is best evaluated by a chromosomal microarray test.

Targeted panels based on “focused exome sequencing” lose the advantages of higher read depth and potential inclusion of high-yield non-coding regions of relevant genes that are provided by “true” targeted panels. However, if initial testing does not reveal a plausible candidate variant, reflex testing to include the entire exome may be pursued.<sup>102-104</sup> Exome sequencing allows for the identification of variants in genes that can cause a phenotype that may mimic an IEI by clinical presentation (e.g., primary ciliary dyskinesia).<sup>108,109</sup>

Exome and whole genome sequencing (**see RECOMMENDATION 3.3**) are preferentially considered over targeted gene panels in two situations. First, for evaluation of patients with IEI and additional phenotypic features that do not involve the immune system (e.g., cardiac malformations, neurologic deficits). These patients may have a higher pre-test probability of immune defects caused by variants in genes not associated with an IEI. As an example, patients with Rubinstein-Taybi syndrome are known to have increased susceptibility to infections and immunologic abnormalities, but the disease is not considered an IEI, and targeted IEI gene panels do not include

*CREBBP*, the gene associated with this condition. Second, exome and genome sequencing are preferred for patients from parents with a high likelihood of consanguinity. Multiple studies suggest that use of broader sequencing platforms in such patients increases the diagnostic yield and may be more cost-effective over targeted gene panel testing.<sup>102, 108, 109</sup>

**RECOMMENDATION 3.3: We suggest whole genome sequencing of individuals with suspected IEI and non-immunologic traits or with high suspicion for a non-coding genetic defect.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Low**

Whole genome sequencing (WGS) is an MPS-based test that sequences the entire genome without an initial capture step. Sequencing data are then aligned to a reference genome, and gene variants are identified and annotated. Based on the vast amounts of data generated, the analysis pipeline may include initially limiting variant evaluation to “panel-like analysis” or “exome-like analysis.” If no plausible candidates are identified in this manner, analysis can be expanded to include non-coding regions.<sup>102-104, 110</sup>

WGS sequencing includes introns and gene regulatory regions that may contain pathogenic variants, and are not covered by targeted panels and exome sequencing. Examples of IEI genes with known pathogenic variants in such non-coding regions include *LRBA*, *DOCK8*, and *ARPC1B*.<sup>110, 111</sup> (**Table 3.3**) The absence of an initial capture step allows for uniform read depth (average read depth approximately 20x-30x), although the limited read depth of WGS does not identify variants with low allele frequencies (*i.e.*, somatic mosaicism). WGS has an enhanced ability to detect CNVs compared to gene panels or exomes.<sup>112</sup> Overall, studies have shown that WGS provides an increase in diagnostic yield over exome sequencing.<sup>113, 114</sup>

WGS is indicated when a patient with suspected IEI remains without genetic diagnosis despite targeted gene panel or exome sequencing, as well as those patients with suspected IEI presenting with non-immunological traits, such as cardiac defect, skeletal malformations and neurological deficits.

**Table 3.3: Examples of IEI genes reported to contain non-coding pathogenic variants**

**RECOMMENDATION 3.4: We recommend DNA copy number variant (CNV) testing in patients with IEL with a suspected gene(s) deletion or duplication.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Detection of gains and losses in DNA can be important for identifying IEL, such as the 22q11 deletion syndrome.<sup>115, 116</sup> CNVs include deletions, duplications, or complex rearrangements of DNA and range in size from 50 to several million base pairs. CNVs account for approximately 12% of the human genome diversity<sup>117</sup> and it is highest in patients with developmental delays.<sup>118</sup> Karyotyping or chromosomal analysis using the G-banding technique with trypsin and Giemsa stain can evaluate large CNVs.<sup>119</sup> This technique is best to identify balanced translocations, unless the translocation breakpoints are known. Chromosomal microarray analysis (CMA), by comparative genomic hybridization (CGH) arrays or single nucleotide polymorphism (SNP) arrays detect small CNVs of at least 400 kb.<sup>120</sup> In general, these methods label genomic DNA from a patient or probes and hybridize them to a control DNA sample. The relative amount of labeled DNA hybridization compared to the control sample is used to determine gains or losses of DNA regions. CMA testing is recommended over fluorescence *in situ* hybridization (FISH) since it has a higher sensitivity to detect microdeletions, such as 22q11.2 microdeletion. As a separate advantage, while karyotyping and FISH are dependent on culturing cells, CMA and MPS based methods can be applied to DNA extracted from any tissue.

MPS-based tests are less sensitive than CMA for detecting changes in one to two exons.<sup>121,122</sup> CMA and MPS-based CNV testing are limited in their ability to detect balanced rearrangements, certain types of repeat expansions, and low levels of mosaicism. CNV testing may yield incidental findings, since entire genomic regions are investigated.<sup>123</sup> CMA also evaluates consanguinity based on the absence of heterozygosity, for regions of homozygosity, or for uniparental disomy.<sup>116</sup>

CNV testing is recommended as a first-tier genetic test for evaluating patients who have developmental delays, intellectual disabilities, or congenital anomalies.<sup>124</sup> It should be performed in a patient with a suspected IEI known to present with gene deletions or duplications. We suggest use of CNV testing to help exclude or confirm pathogenic variation in the opposite allele in patients who have one pathogenic variant in a gene that causes disease in an autosomal recessive manner.<sup>102</sup>

**RECOMMENDATION 3.5: We recommend the American College of Medical Genetics and Genomics (ACMG) guidelines for evaluating gene variant pathogenicity.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

The ACMG publishes guidelines for gene variant classification and interpretation with improvements, modifications, and updates.<sup>102, 123, 125</sup> These guidelines are meant to serve as a framework for evaluating gene variant pathogenicity rather than as stringent criteria.

Using ACMG guidelines, gene variants are classified as one of five categories: benign, likely benign, variant of uncertain significance, likely pathogenic, and pathogenic. Criteria for classification are determined by evidence including population frequency, laboratory testing of patient samples, and *in silico* prediction algorithms. Because genetic conditions differ mechanistically, molecularly and clinically, gene-specific interpretations are recommended.<sup>126</sup> Although such specifications are being developed for many genes, few currently exist for IEI.<sup>127,128</sup> One caveat is that the ACMG criteria for pathogenicity favor the identification of loss-of-function rather than gain-of-function genetic mechanisms. For example, nonsense, frameshift, canonical splice site, and exonic deletions are favored for asserting pathogenicity, because these types of variants most often generate loss of function diseases.

Providers should note that a gene variant classification in a clinical report may not account for gene-specific factors.<sup>102</sup> A distinction must be made between variant classification and clinical interpretation.<sup>129</sup> Clinical interpretation of a variant may be understood in terms of pre-test probability and likelihood ratio, which together determine post-test probability (as depicted by Fagan's nomogram).<sup>130</sup> Pre-test probability reflects

how likely a gene defect specified by the test report explains the phenotype of the patient. Such estimations are based on clinical expertise and information from scientific and medical resources. The assessment must account for potential or known heterogeneity in disease presentations associated with the gene, particularly when diverse pathogenesis models (e.g., gain-of-function, haploinsufficiency, dominant-negative loss-of-function, or neomorphic molecular function) are possible. The likelihood ratio of pathogenicity is determined by the ACMG-based variant classification. Reclassification by the clinical provider may be necessary due to information not considered by the laboratory or in accordance with application of gene-specific modifications to the ACMG guidelines.<sup>130</sup> The post-test probability is then ascertained from the pre-test probability and likelihood ratio to provide a clinical interpretation of the variant.

For example, when genetic testing in a male infant with agammaglobulinemia and absent B cells reveals the presence of a variant in *BTK*, clinical expertise suggests a high pre-test probability that this patient has *BTK* deficiency. If the variant is reported as a variant of uncertain significance, likely pathogenic, or pathogenic, the post-test probability remains high, supporting that the variant is responsible for the phenotype. If it is classified as benign or likely benign, it follows that the *BTK* variant is not likely to explain the disease. In a female infant with SCID, a monoallelic pathogenic variant in *JAK3* (a known gene associated with AR- SCID) would be clinically important because of the high pre-test probability given the diagnosis, suggesting an undetected pathogenic variant on the other allele. In another example, a likely pathogenic variant in *COPA* identified incidentally in a completely healthy adult would be interpreted as unlikely to be clinically relevant for that individual, because the pre-test probability is low. This interpretation is with the caveat that a person can be asymptomatic (or “pre-symptomatic”) at the time of evaluation but develop disease later.

**RECOMMENDATION 3.6: We recommend familial genetic testing to aid in gene variant pathogenicity resolution.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

The sequencing of both biological parents together with the proband (known as “trio analysis”) defines maternal-, paternal-inherited or *de novo* variants, and may help to determine whether potentially compound heterozygous gene variants are located in *cis* or *trans*.<sup>102-104</sup> For example, if two variants are identified in a gene that causes IEI due to biallelic defects (i.e., autosomal recessive), these may not be located on opposite alleles. In situations when a parent is unavailable, testing of a parental relative or an offspring of the patient may be informative. Because penetrance of gene defects might

not be 100%, segregation of candidate variants with disease in affected family members should not be assumed.<sup>131</sup>

Genetic testing for X-linked IEI disorders should also be considered in females. Extreme skewing towards the X chromosome carrying the pathogenic allele can lead to disease, and has been described in CGD, WAS, XLA and other IEI.<sup>132-136</sup> In some X-linked IEI, female carriers can have health issues even without X-chromosome skewing.<sup>137,138</sup>

**RECOMMENDATION 3.7: We suggest familial genetic testing to ascertain risk of disease in currently unaffected relatives.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Low**

Some IEI are known to have variable penetrance and clinical presentation in different individuals carrying the same pathogenic gene variant, such as *CTLA4* haploinsufficiency and *STAT1* gain of function.<sup>139, 140</sup> Awareness of a genetic diagnosis in unaffected relatives can facilitate monitoring for possible future development of the disease in family members who are healthy at the time of genetic testing.<sup>131</sup>

For unaffected minors, decisions for genetic testing should weigh whether the results will have an immediate beneficial impact on their health or whether testing can be delayed until adulthood for consent of testing. In IEI disorders mediated by biallelic and X-linked variants, carrier testing is useful to determine recurrence risk and to assist with family planning.<sup>141</sup>

**RECOMMENDATION 3.8: We recommend investigating multiple genetic diagnoses when a monogenic diagnosis does not explain the patient's clinical characteristics.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

Multiple genetic diagnoses can be present within an individual and produce a blended phenotype consisting of completely distinct, partially, or completely overlapping features.<sup>142</sup> For genetic diseases overall, additional genetic defects are found in approximately 5% of patients with one genetic diagnosis.<sup>143</sup> In patients with IEI, the multiple molecular diagnosis rate is higher, ranging from 9% to 11% of diagnosed patients.<sup>90, 116</sup> Broad genetic testing is indicated when the initial identified gene defect does not explain all of the patient's clinical presentation. Providers should especially weigh the potential for a blended phenotype in patients who appear to have an "atypical" or "expanded" presentation of a single genetic condition.

**RECOMMENDATION 3.9: We recommend that genetic testing for patients with IEI can be ordered by clinicians with expertise in IEI diagnosis.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

Clinical immunologists have dedicated training in recognizing both the clinical phenotypes related to IEI and defects of genes and pathways of the immune system that can cause disease. Clinicians trained in IEI have the necessary expertise to determine appropriate genetic testing for patients with suspected IEI and provide appropriate genetic counseling.<sup>19, 90, 102-104, 110, 116</sup> Collaboration with a geneticist or genetic counselor is helpful but not required for obtaining such testing, and testing restrictions could delay diagnosis and treatment, with occurrence of comorbidities.

#### **SECTION 4. Immunologic diagnosis of predominantly antibody deficiencies.**

**RECOMMENDATION 4.1: We recommend that patients with suspected antibody deficiencies be evaluated with immunoglobulin measurement, antigen- specific antibody responses and lymphocyte phenotyping, and exclusion of secondary causes.**

Strength of recommendation – **Strong.**

Certainty of evidence- **High**

Assessment of serum immunoglobulin levels (IgG, IgA, and IgM) is recommended as first-tier in the diagnostic work-up of patients with suspected antibody deficiency. The interpretation of these test results should take into consideration age-specific and laboratory specific normal reference ranges and whether there are secondary causes of antibody deficiency.

An IgG level less than 2 standard deviations below the age-appropriate reference mean for 2 measurements more than 3 weeks apart is considered by international consensus guidelines to be low.<sup>144-146</sup> If the IgG level is very low at time of first measurement (<100-300 mg/dL depending on age), then a single measurement may be appropriate in terms of expediting the subsequent clinical testing and management.<sup>144</sup>

Secondary causes of antibody deficiency include medication-induced (e.g., concomitant use of corticosteroids at the time of testing and prolonged effects from B cell depleting therapeutic agents), and neoplastic disease, particularly in patients with adulthood-onset history of frequent infections.<sup>147</sup> Causes of protein and antibody losses, such as nephrotic syndromes, protein-loss enteropathies, lymphangiectasias, or inflammatory bowel disease with low serum IgG and low serum IgM have been well described.<sup>148</sup>

Supporting laboratory evidence for protein loss includes low serum albumin level,

proteinuria, and/or protein losses in the stool (e.g., a positive stool alpha-1-antitrypsin level).

An assessment of total peripheral blood counts of CD19+ B cells, CD3+ T cells, CD4+ T cells, CD8+ T cells, and CD16/56+CD3- NK cells is necessary to identify combined immune deficiency (**see Section 5**) and congenital agammaglobulinemia (**see RECOMMENDATION 4.2**). This diagnostic clarity has direct implications on patient clinical management.

An assessment of peripheral blood B cell subsets, in particular class-switched memory (CD27+IgD-/IgM-) B cells, is recommended for patients with antibody deficiencies. Absent memory B cells is a component diagnostic criterion for common variable immune deficiency (CVID) using the European Society for Immunodeficiency (ESID) guidelines.<sup>146</sup> Patients with low class-switched memory B cells (defined as <2% of total CD19+ B cells) do not produce protective antibody levels following vaccination, including to the COVID mRNA vaccines,<sup>149</sup> and are at high risk for the development of auto-inflammatory disease co-morbidities,<sup>150</sup> and death.<sup>150, 151</sup> Expansions of early transitional B cells (defined as IgD+CD27-CD10+ or IgD+CD27-CD24hiCD38hi) or activated CD21lo B cells are associated with the occurrence of autoimmune and end-organ inflammatory disease.<sup>150, 152</sup>

An assessment of peripheral blood T cell subsets may contribute to the diagnostic evaluation of antibody deficiency. T-cell abnormalities in number and function are frequently found in patients with CVID.<sup>153-155</sup> The diagnosis of some of these patients may be revised after genetic testing to other IEI, in particular several forms of T regulatory cell dysfunction (Tregopathy) syndromes (e.g., CTLA4 deficiency)<sup>156, 157</sup>

Normal serum immunoglobulin levels do not rule out a diagnosis of humoral immune dysfunction. **RECOMMENDATION 4.6 and 4.7** detail specific antibody deficiency (SAD), a condition in which patient antibody levels (total IgG) are normal, however, antigen-specific antibody response to immunization is decreased. Patients with SAD are susceptible to frequent infections - predominantly at ears, sinuses, lung, and/or gastrointestinal locations - similarly to patients with low serum IgG levels.

Vaccines do not uniformly elicit high serum antibody titers, and some are not recommended for routine clinical assessment of vaccine responsiveness, such as the hepatitis B vaccine.<sup>158</sup> Testing of antigen-specific antibody response to immunization has historically centered around testing of both T-dependent vaccine responses (e.g., HiB and tetanus toxoid) and T-independent vaccine responses (e.g., pneumococcal 23 serotype polysaccharide vaccine).<sup>159</sup> With use of the new 15-, 20- and 21-valent conjugated pneumococcal vaccines becoming widespread in routine clinical care, testing of vaccine responsiveness is evolving (**RECOMMENDATION 4.6 and 4.7**).

Guidelines for the analysis of anti-pneumococcal antibody responses suggest using 1.3 ug/mL following a polysaccharide pneumococcal vaccine and 0.35 ug/mL following a pneumococcal conjugate vaccine as thresholds to determine protective pneumococcal serotype-specific antibody levels against invasive pneumococcal infections. These testing are measured at baseline, 4-week post-vaccination, and, to assess persistence of immunological memory, at 6 months post-vaccination.<sup>159</sup> Testing pre- to post-immunization antibody titers to pneumococcus serotypes should be performed by the same clinical laboratory for diagnostic accuracy. Results vary widely by reference laboratory with discordance in micrograms per milliliter reported.<sup>160</sup>

**RECOMMENDATION 4.2: We recommend the diagnosis of agammaglobulinemia for patients with low or undetectable serum immunoglobulin concentrations *and* low or undetectable circulating B cells *and* normal total CD3+ T cell numbers.**

Strength of recommendation- **Strong**

Certainty of evidence – **High.**

Patients with agammaglobulinemia present with recurrent bacterial respiratory tract infections, particularly otitis media, sinusitis, and pneumonia in the first 2 years of life.<sup>161-163</sup> The most common organisms isolated are *S. pneumoniae* and *H. influenzae*. Other reported infections in agammaglobulinemia include those by enterocytopathic human orphan (ECHO) viruses and ecthyma or pyoderma gangrenosum caused by species of *Helicobacter* and *Campylobacter*. Rarely, patients present with pneumocystis pneumonia or vaccine strain poliovirus infection.<sup>164, 165</sup> *Ureaplasma* or *Mycoplasma* species-related arthritis and bacteremia or regional enteritis associated with enterovirus are also seen.<sup>165-167</sup> Some patients are not recognized to have agammaglobulinemia until after 5 years of age.<sup>167, 168</sup>

The physical examination of patients with agammaglobulinemia usually reveals absence of lymph nodes and tonsils distinct from other forms of antibody deficiency. There are no other consistent physical findings in patients with agammaglobulinemia.<sup>161</sup>

Agammaglobulinemia is characterized by a serum IgG level of usually less than 100 mg/dL, low or undetectable serum IgM and serum IgA levels, and peripheral blood CD19+ B-cell counts of less than 2%.<sup>161, 162</sup> The differential diagnosis of agammaglobulinemia include secondary causes and severe CVID (see below) with serum immunoglobulins levels and B cells in the agammaglobulinemic range. It can be difficult to distinguish agammaglobulinemia from CVID without molecular testing. Measurement of antigen-specific antibodies titers is not necessary in patients with IgG levels less than 150 mg/dL.

Genetic evaluation is recommended in the diagnosis of agammaglobulinemia (**see Section 3**). Approximately 85% of patients with agammaglobulinemia patients have the

X-linked form (XLA), associated with variants in *BTK* encoding Bruton's tyrosine kinase (BTK).<sup>161, 169</sup> The absence of BTK protein in monocytes or platelets can be demonstrated by Western blotting or flow cytometry. Patients with certain *BTK* variants can have milder clinical and immunologic phenotypes with higher concentrations of serum immunoglobulins suggestive of CVID or even specific antibody deficiency (SAD).<sup>162</sup> A family history of affected maternal male cousins, uncles, or nephews suggestive of X-linked inheritance may be present, although sporadic cases are common. Pathogenic variants in one of several genes that regulate B-cell maturation cause autosomal recessive agammaglobulinemia.<sup>169-172</sup> These genes encode components of the pre-B-cell immunoglobulin receptor, including IgM heavy chain (*IGHM*), the surrogate light chain (*IGLL1*), the immunoglobulin receptor-associated signal transducing chains Igα and Igβ (*CD79A*, *CD79B*), the cytoplasmic adapter molecule B-cell linker protein (*BLNK*), and the downstream PI3K signaling pathway. Autosomal dominant monogenic agammaglobulinemias are reported associated with variants in *TCF3*, *TOP2B*, and *SPI1*.<sup>173-175</sup>

**RECOMMENDATION 4.3: We recommend the diagnosis of CVID for patients with low serum IgG and low serum IgA and/or low serum IgM levels and demonstrated impaired antibody response to infection or immunization.**

Strength of recommendation: **Strong**

Certainty of evidence: **High.**

CVID may be the most frequently encountered symptomatic IEL, affecting an estimated 1:30,000 individuals, though prevalence among specific populations may vary with a particularly high prevalence described in Northern Europe.<sup>176, 177</sup> The typical clinical presentation for these patients is recurrent sinopulmonary infections, but CVID may be diagnosed after recurrent autoimmune cytopenias, benign lymphoid hyperplasia, or chronic gastrointestinal disease.<sup>144</sup> Patients with hypogammaglobulinemia and thymoma should be given a diagnosis of Good syndrome.<sup>178</sup>

Bacterial infections are frequent in CVID, including common respiratory infections caused by *S. pneumoniae* and non-typeable *H. influenzae* as well as atypical pneumonia caused by *Mycoplasma* and *Ureaplasma* species that also include joint involvement.<sup>179</sup> Respiratory tract infections with viruses are common.<sup>180</sup> Gastrointestinal infections may be frequent and refractory to treatment, including parasitic (such as *Giardia*) and viral (such as norovirus) infections (**Section 9**).<sup>181</sup>

In addition to infections, CVID patients may present with autoimmunity, chronic gastrointestinal, liver, and lung disease and malignancy. Autoimmunity most frequently manifests as cytopenias, though other forms, such as arthritis, also occur.<sup>182</sup> Frequent chronic gastrointestinal complications include gastritis and enteritis, which may have pathological appearance of autoimmune inflammation but absent autoantibodies

typically found in these diagnoses.<sup>183, 184</sup> Liver disease shows nodular regenerative hyperplasia on biopsy, a condition with unclear etiology and challenging clinical course.<sup>185</sup> Chronic lung disease in CVID presents as asthma, chronic obstructive pulmonary disease, or bronchiectasis.<sup>186</sup> Interstitial lung disease may be present, characteristically displaying benign lymphoid hyperplasia pathology together with granulomatous inflammation and thus described as granulomatous-lymphocytic interstitial lung disease (GLILD).<sup>187</sup> Lymphoproliferation in the lung often coincides with lymphoproliferation elsewhere, such as the lymph nodes or spleen.<sup>188</sup>

It is now estimated that around 30% of CVID cases have identifiable genetic etiology.<sup>189, 190</sup> Widespread availability of clinical genetic testing is at the forefront of CVID clinical care. As examples, heterozygous pathogenic variants of *CTLA4* and homozygous pathogenic variants of *LRBA* both reduce expression of CTLA-4, a key regulator of T cell responses, leading to an autoimmune and lymphoproliferative disease as well as varying degrees of antibody deficiency consistent with CVID.<sup>191, 192</sup> Also, heterozygous gain-of-function variants of *PIK3CD* and loss of function variants of *PIK3R1* result in similar immune disorders marked by a CVID-like clinical presentation of autoimmune cytopenias, lymphoid hyperplasia, and antibody deficiency termed activated phosphoinositide 3-kinase delta syndrome (APDS).<sup>193</sup> IgG replacement therapy (**Section 8**) should be initiated in those diagnosed with CVID.

**RECOMMENDATION 4.4: We recommend the diagnosis of selective IgA deficiency (SIGAD) for patients older than 4 years of age with serum IgA below the limit of detection *and* normal serum IgG and IgM levels.**

Strength of recommendations: **Strong**

Certainty of evidence: **High**.

SIGAD is relatively common with a prevalence of about 1:500 in Caucasians and appears to be less common in Asian populations, where the prevalence is reported between 1:3000 to 1:18000.<sup>194, 195</sup> Assays at most clinical laboratories have not been sensitive enough to measure IgA levels below 7 mg/dL, and about one third of SIGAD patients are thought to have completely absent serum IgA.<sup>3</sup> Four years of age is considered the time when most children reach the normal range for serum IgA level. SIGAD patients may evolve into CVID later in life.<sup>196, 197</sup>

Genetic determinants of SIGAD are not well defined; it has been associated with variants in MHC loci, *TNFSRF13B*, and in other genes.<sup>198</sup> Patients with SIGAD can be asymptomatic; however, a subset of them may present with frequent infections (27%), atopy (23%) or autoimmunity (14%).<sup>199</sup> SIGAD should be considered in the evaluation of celiac disease as it can give false negative results on IgA-based antibody tests. Presence of SIGAD may increase the likelihood of an alternative cause for villus atrophy

other than celiac disease, such as Giardia infection or small intestinal bacterial overgrowth.<sup>200</sup>

**RECOMMENDATION 4.5: We suggest the diagnosis of IgG subclass deficiency for patients with recurrent infections *and* low levels of one or more serum IgG subclass levels (IgG1, IgG2 or IgG3 and excluding IgG4) *and* normal serum total IgG level.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Moderate.**

Patients with recurrent infections may present with normal total IgG level with low serum levels of one or more of the four IgG subclasses. IgG1 is the most abundant subclass (70-80% of total IgG), and IgG1 serum levels correlate with total IgG serum levels. IgG2 follows in abundance with 20-30% of total IgG levels. IgG3 represents about 10% of total IgG and has the shortest half-life at 7 days, compared to 21 days for the other subclasses. IgG4 is the least abundant (less than 1% of total IgG), and its role against infections has not been defined.

The genetic and molecular basis of IgG subclass deficiencies have not yet been defined, although associations with IEI have been reported. IgA deficiency infrequently occurs concurrently with IgG2 subclass deficiency, and such individuals may have worse clinical course than those with either immunological finding alone.<sup>201</sup> More than half of activated PI3K delta syndrome (APDS) patients with normal total IgG levels may have IgG2 subclass deficiency.<sup>202</sup> A prospective study of 49 children with IgG2 subclass deficiency, predominantly boys, showed increased frequency of respiratory infections, compared with age-matched healthy controls.<sup>203</sup> Healthy children may have IgG2 subclass deficiency without presenting with increased frequency of infections.<sup>204</sup>

**RECOMMENDATION 4.6: We suggest the diagnosis of specific antibody deficiency (SAD) to polysaccharides for patients with recurrent respiratory infections *and* impaired antibody responses to polysaccharides *and* normal serum IgG levels.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Moderate.**

Patients with SAD to polysaccharides have recurrent infections and normal antibody responses to protein antigens and have normal responses to conjugate polysaccharide vaccines, but the antibody response to a booster dose of the 23-valent unconjugated pneumococcal polysaccharide vaccine is impaired, defined as non-protective antibody levels when measured after 4 weeks after immunization. The molecular and immunological mechanisms for this condition have not been defined.

In patients who already have protective levels to some pneumococcal serotypes due to prior vaccination with conjugated polysaccharide vaccines, serotypes present in the unconjugated pneumococcal polysaccharide vaccine but not in the conjugated vaccine are used for diagnostic evaluation. Widespread pediatric use of the most recently approved 20-valent conjugated pneumococcal vaccine limits the utility of diagnostic challenge with the 23-valent unconjugated pneumococcal polysaccharide vaccine, as only 4 serotypes are present in the 23-valent vaccine that are not in the 20-valent vaccine (serotypes 2, 9N, 17F, 20). Serotype 6A is included in the 20-valent conjugated vaccine but not in the 23-valent unconjugated polysaccharide vaccine. Usage of the unconjugated *Salmonella* vaccine has been proposed as an alternative vaccine for diagnosis of SAD to polysaccharide antigens, but its unclear diagnostic value limits clinical utility.<sup>205</sup>

Results of anti-pneumococcal antibody testing, including percentage of positive results, can vary between clinical laboratories.<sup>160, 206</sup> Previous guidelines with regards to protective antibody levels against invasive pneumococcal infection recommended using anti-pneumococcal serotype specific capsular antibody titers of 1.3 µg/mL or greater after unconjugated polysaccharide vaccine and 0.35 µg/mL for response to conjugated vaccine.<sup>159</sup> A response to immunization of less than 50% of the measured anti-serotype antibodies at protective levels is a cut-off for diagnosis of SAD.

It is suggested to use first the unconjugated pneumococcal vaccine (PSV23) to evaluate T cell-independent antibody responses then, if the response is suboptimal administer one of the conjugated vaccines. As an alternative, the evaluation of SAD may be accelerated by moving directly to conjugated pneumococcal vaccine after assessing pre-vaccination pneumococcal antibody levels. While this approach will not identify those who have inadequate antibody responses to the unconjugated vaccine, it provides with an intervention that might result in a decrease in the frequency of infections, other than antibiotic prophylaxis and IgG replacement (**see Sections 8 and 9**), and may allow for diagnosis of SAD to protein antigen (**see RECOMMENDATION 4.7**).

**RECOMMENDATION 4.7: We suggest the diagnosis of specific antibody deficiency (SAD) to protein antigen for patients with recurrent infections *and* impaired antibody responses to protein antigen immunizations *and* normal serum total IgG levels.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Low**.

While SAD has historically referred to patients with recurrent infections and antibody deficiency for pneumococcal polysaccharide antigens, the increased use of 20-valent conjugated pneumococcal vaccination and greater awareness of immune defects

necessitate broader consideration of SAD diagnosis. Inability to respond to specific antigens other than pneumococcal polysaccharides in the context of normal serum immunoglobulin levels is not well recognized.

Individuals with recurrent infections and normal total serum IgG levels who have impaired antibody responses to highly immunogenic vaccines but no other immunological defects may receive the diagnosis of SAD to those protein antigens. Examples of highly immunogenic vaccines include those for tetanus or diphtheria, in which nearly 100% of immunocompetent individuals immunized develop protective antitoxin antibodies, and varicella, which has 98% or more seroconversion in individuals who have completed the vaccine series. In contrast, hepatitis B vaccination has significantly lower immunogenicity.<sup>207</sup>

**RECOMMENDATION 4.8: We recommend that patients with low serum IgG and IgA levels *and* normal or elevated serum IgM level be given the diagnosis of immunoglobulin class-switch defects *after* ruling out combined immunodeficiencies that present with similar laboratory findings**

Strength of recommendation: **Strong**

Quality of evidence: **High**.

Immunoglobulin class-switch defects have been known as hyper-IgM syndromes (HIGM), because often, but not always, serum IgM is elevated. Deficiencies of activation-induced cytidine deaminase (AID), uracil nucleoside glycosylase (UNG), and mutator S homolog 6 (MSH6) clinically present similarly to other forms of antibody deficiency, with recurrent upper and lower respiratory tract infections in childhood.<sup>209-211</sup> These patients may also develop nonmalignant lymphoid hyperplasia, which occurs in approximately 70%.<sup>211</sup> Autoimmune and inflammatory disorders (e.g., autoimmune hemolytic anemia and inflammatory bowel disease) can be seen in approximately 20% of patients with a deficiency of AID.<sup>212</sup>

The total numbers of B cells and non-switched memory B cells (CD27+IgD+IgM+) are normal, whereas numbers of class-switched memory B cells (CD27+IgM-IgD-) are reduced.<sup>211</sup> Expansion of germinal centers occurs in peripheral lymphoid tissue from these patients.<sup>208</sup> T cells counts and T cell proliferation are typically normal and are helpful to rule out combined immunodeficiencies (CID), such as CD40 ligand deficiency and NEMO deficiency (**See Section 5.1**). We recommend genetic testing because of potential implications in prognosis. IEI presenting with similar screening laboratory findings also include CVID (**RECOMMENDATION 4.3**) and, in adults, monoclonal gammopathy of uncertain significance (MGUS) should be considered as a masquerading secondary immunodeficiency, as approximately 15% of MGUS presents with elevated IgM.<sup>213</sup>

**RECOMMENDATION 4.9: We recommend the diagnosis of transient hypogammaglobulinemia of infancy (THI), for infants and children with low serum IgG level *and* normal antibody response to immunizations *and* absent evidence of secondary causes**

Strength of recommendation: **Strong**

Certainty of evidence: **High**.

Infants have transplacentally-acquired maternal IgG for the first 3 to 6 months of life until it is metabolized. In some infants, production of IgG (and in some cases IgA and IgM) does not reach normal levels until early childhood. Prematurity might result in limited maternal IgG transplacental transfer and contribute to low serum IgG levels in the infant or toddler. This period of hypogammaglobulinemia can be associated with recurrent respiratory infections.<sup>214-216</sup> THI is a diagnosis of exclusion made in the absence of other immune deficiency diagnoses, and in retrospect once serum IgG levels reach normal range. Antigen-specific antibody responses and cellular immunity are usually preserved but may be incomplete. In one prospective study of 18 patients with THI, IgG levels spontaneously corrected to normal at a mean age of 27 months, with all patients at normal levels by 59 months.<sup>217</sup>

There is no known genetic basis for THI, although an increased incidence is reported in families with other immunodeficiencies, particularly *IGLL 1* deficiency.<sup>218</sup> Some THI patients have reduced memory B-cell counts.<sup>219, 220</sup> We recommend measuring serum IgG levels every six months until these levels are in normal range for age. Although most children with THI spontaneously recover their IgG levels and have a benign clinical course, some of them do not recover and are diagnosed with CVID, or other forms of antibody deficiency.<sup>214-217</sup>

**RECOMMENDATION 4.10: We suggest the diagnosis of unspecified primary hypogammaglobulinemia for patients with significant morbidity from infections *and* low serum IgG level *and* normal cellular immunity *and* no evidence of secondary causes of low IgG levels *and* not fulfilling diagnostic criteria for the above antibody deficiency disorders.**

Strength of recommendations: **Conditional**

Certainty of evidence: **Moderate**.

A diagnosis of unspecified primary hypogammaglobulinemia can be given to patients who have (1) low levels of serum immunoglobulins not conforming to any of the diagnoses above, (2) significant morbidity from infections, (3) normal cellular immunity, (4) no other potential immune deficiency diagnosis, and (5) no other conditions predisposing to humoral immunodeficiency, including secondary immunodeficiencies (See **RECOMMENDATION 4.1**).<sup>147, 216, 217</sup>

**SECTION 5. Combined Immunodeficiencies, Neutrophil Defects, Innate Immune Defects and Complement Deficiencies.**

**RECOMMENDATION 5.1: We recommend immunological investigations in patients with infectious manifestations, autoimmunity, malignancy, or organ-specific pathologies suggesting cellular and humoral immunodeficiency.**

Strength of recommendation: **Strong**

Certainty of evidence: **High.**

General evaluation of immune phenotype and function is necessary to support detailed clinical history and physical exam for the assessment of suspected combined immunodeficiency (CID). While clinical presentation of CIDs can be variable and include infectious manifestations, autoimmunity, malignancy, and organ-specific pathologies, they share the common feature of presenting with both cellular and antibody defects. It is essential that immunology test results are reported with appropriate age-specific reference intervals.<sup>220</sup> The following testing is indicated in IEI, depending on clinical presentation. The list is not exhaustive and both additional testing and new applications of current testing are likely to be established in the future. A list of laboratories performing specialized immunology testing is available at URL: <https://cis/clinimmsoc.org/dli/test-directory.php>

**Complete Blood Count with Differential (CBCd):** CBCd is informative in all patients with suspected CID. Lymphopenia, defined as an absolute lymphocyte count (ALC) below the normal range for age (e.g., <1000 cells/ $\mu$ L in adults or <2500 cells/ $\mu$ L in infants), is characteristically found in CIDs. Cytopenias are frequently part of the clinical spectrum of CIDs [e.g., neutropenia in CD40 Ligand (CD40L)<sup>222</sup> and thrombocytopenia in Wiskott Aldrich Syndrome (WAS)].<sup>223</sup>

**Serum immunoglobulin levels and quantitative specific antibody titers:** Abnormal immunoglobulin levels and low or absent antibody responses to immunizations are frequent in CIDs. Serum immunoglobulin levels must be interpreted in the context of age-appropriate reference intervals (**see Section 4**). Reference intervals represent the mid-95 percentile of a healthy population and therefore 5% of this population will have values below or above the middle 95%, and thus, clinical significance may not be based only on numerical cut-offs.

**Lymphocyte subset phenotyping:** A hallmark of most CIDs is low percentages of T and sometimes B cells, both of which can vary depending on the specific underlying genetic cause and degree of immune activation at the time of blood sampling. Additionally, lymphocyte counts are influenced by age, sex, circadian rhythms and diurnal variation.<sup>225, 226</sup> Lymphocyte subset (T/B/NK) phenotyping includes quantification

of the relative percentages and absolute numbers of T cells (CD3+, CD3+CD4+, CD3+CD8+), B cells (CD19+, CD20+), and natural killer (NK) cells (CD16+CD56+) by flow cytometry. Markers for T/B/NK panels may include (1) CD45 for identification of nucleated blood cells and for accurate discrimination of lymphocyte, monocyte, and neutrophil populations, (2) CD14 for identifying monocytes, (3) CD3, CD4 and CD8 for T cell subset identification and enumeration, (4) CD19 and/or CD20 for identification of B cells, and (5) CD56 and CD16 for the identification of NK cells. The ratio of CD4:CD8 T cells may also be reported. Significant discrepancies between the percentage of CD3+ T cells and the sum of CD4 and CD8 T cells percentages should be investigated for increases in double-negative T cells (DNTs), which may express either T cell receptor (TCR)  $\alpha\beta$ +, seen in certain lymphoproliferative conditions including Autoimmune Lymphoproliferative Syndrome (ALPS),<sup>227</sup> or TCR  $\gamma\delta$ +, which occur with viral and mycobacterial infections, and is associated with CID (e.g., Ataxia Telangiectasia [A-T]).<sup>228</sup> A low CD4:CD8 ratio may be indicative of MHC Class I or ZAP70 deficiency,<sup>229, 230</sup> where CD8 T cells are significantly low or MHC Class II deficiency where CD4 T cells are significantly low.<sup>231</sup> B cell counts are low in a variety of CIDs (e.g., ICOS deficiency, NBS1 deficiency).<sup>231, 232</sup>

**Naïve and memory T cells, and recent thymic emigrant (RTE) phenotyping.** The percentage of naïve T cells (CD4+CD45RA+ and CD8+CD45RA+) and RTEs (CD4+CD31+CD45RA+ and CD8+CD31+CD45RA+) is highest in newborns (>80%) and decreases with age. Conversely, activated/memory T cells (CD4+CD45RO+ and CD8+CD45RO+) increase with age, reflecting antigen exposure and development of T cell memory response. T cell phenotyping panels include a variety of markers to differentiate naïve, memory, effector memory T cells (Tem), central memory T cells (Tcm), and terminally differentiated memory T cells re-expressing CD45RA (TemRA). Quantification of these populations is useful for assessing an ongoing T cell mediated immune process (e.g., an unexpected increase in effector memory T cells may indicate a T-cell mediated reactive or autoreactive process). TemRA cells are a heterogeneous subset and represent preformed effector cells with high expression of effector molecules. If they express CD57 they can represent a “pre-exhaustion” or senescent phenotype. CD8+ TemRA cells can expand with age and are also increased in chronic viral infections and chronic antigenic stimulation. CD4+TemRA cells have been implicated in protective immunity against viral pathogens. Defective T cell memory development is observed in a variety of CIDs.<sup>233, 234</sup> RTEs correlate with TREC levels (**See Section 2**), and are reduced in severe CIDs and in congenital athymia.<sup>65, 235</sup>

**B cell phenotyping:** B cell phenotyping panels include markers (CD19 and/or CD20, IgD, CD27, IgM, CD24, CD21, CD38, CD10, IgG, IgA), to assess the relative frequencies of naïve, memory, class-switched and non- class-switched (marginal zone) memory, transitional, CD21-/low(or dim) B cells and plasmablasts.<sup>236</sup> Additional phenotyping may include quantification of IgM, IgD, IgG and IgA-expressing B cells, as

well as CD10+ immature B cells. These analyses are useful for assessment and diagnosis of CIDs with perturbation of immunoglobulin levels or defective antibody responses, such as decreased class-switched memory B cells (CD40L, CD40 deficiency),<sup>237</sup> or increased CD21-/low B cells as a correlate of autoimmune complications in CIDs.<sup>187-189</sup>

**Quantification of regulatory T cells (Treg):** Tregs (CD4+CD127loFOXP3+CD25hi) constitute approximately 5-10% of peripheral blood CD4+ T cells.<sup>238</sup> Although low in frequency, Tregs are a crucial component of immune regulation. Low Treg numbers are associated with immune dysregulation (lymphoproliferation, autoimmune cytopenias, organ-specific autoimmunity) in a variety of CIDs (e.g., *DOCK8* pathogenic variants).<sup>239</sup> Treg function testing is not clinically available. Of note, the CD4+CD25hiCD127lo phenotype (without measuring FOXP3 expression) may not accurately identify Tregs<sup>240</sup> and FOXP3 can be transiently expressed in activated T cells that are not Tregs.<sup>241</sup>

**Quantification of T Follicular Helper Cells (Tfh):** Tfh (CD4+CXCR5+PD1hi ICOS+BCL6+) are orchestrators of long-lived antibody responses.<sup>242</sup> These cells are classically found in germinal centers (GC) of secondary lymphoid organs with a small population (~10%) found in peripheral circulation. IEI resulting in defective GC formation (e.g., *CD40L*, *ICOS*, *IL-10R*, *NEMO*)<sup>243</sup> are associated with low frequencies of Tfh. Elevated numbers of Tfh may occur in CID with autoantibody production,<sup>244</sup> including those with autoimmune cytopenias.<sup>245</sup>

**Quantification of activated, exhausted, senescent T cells:** CIDs associated with an underlying dysregulated immune process or impaired T cell responses may present with an increase in activated, exhausted and/or senescent T cells. A variety of cell surface markers are used to quantify these cell populations including but not limited to, HLA-DR and a combination of HLA-DR and CD38 for activated T cells, CD57 for senescent T cells, and PD-1 for exhausted T cells. Activated T cells may be increased in CIDs with decreased Treg function (e.g., *STAT5b* deficiency)<sup>246</sup> and immune dysregulated processes (e.g., *DOCK8* deficiency).<sup>247</sup> Patients with CIDs associated with chronic or refractory viral infections may have increased HLA-DR+CD38+ activated T cells. Expansion of senescent CD8+ T cells is observed in patients with activated p110-delta syndrome (APDS).<sup>248</sup> T cell exhaustion can be observed in the context of chronic antigenic stimulation, especially persistent viral infections.<sup>249</sup> Monitoring the relative frequencies of these cell populations is useful for diagnosis and when assessing responses to therapy.

**Assays for T cell proliferation to mitogens and antigens:** The capacity of T cells to respond and proliferate when exposed to an antigen in the presence of either MHC class I or class II on antigen-presenting cells (APCs) is crucial for an effective adaptive immune response. Due to limited exposure to foreign antigens, and prior to immunization with routine childhood vaccines (before two months of life), evaluation of

the antigen-specific T cell response in newborns may not be informative. Pan- T cell stimulants, or mitogens, such as the plant lectins phytohemagglutinin (PHA), concanavalin A (ConA) and pokeweed mitogen (PWM) are used to test T cell capacity to proliferate. In addition to these mitogens, T cells can be stimulated to proliferate via antibody crosslinking of the CD3 complex and costimulation with anti-CD28 antibody, or the addition of exogenous IL-2. Anti-CD3 stimulation with IL-2 or CD28 is particularly useful when assessing signaling defects downstream of the T cell receptor, or due to defective IL-2 production or response (e.g., WAS).<sup>250</sup> Also, stimulation with anti-CD3 and other costimulants as described above offers a more physiological yet global assessment of the T cell proliferative response compared to mitogen stimulation. T cell proliferative responses to antigens are commonly measured after exposure to tetanus toxoid or candida. Defective T cell proliferation in response to mitogenic stimulation is a feature of several CIDs, including ZAP70 deficiency, MHC Class II deficiency and calcium channel defects, among others.<sup>251</sup>

While the well-established radiometric method based on incorporation of tritiated thymidine is still widely used in many clinical laboratories for T cell proliferation assays, this method may not discriminate between normal and defective T cell function in severely lymphopenic patients. In these patients, the use flow cytometry methods that identify CD3+ T cells and use DNA-intercalating fluorescent dyes to identify dividing cells is most specific for the assessment of T cell proliferation.<sup>252</sup>

**RECOMMENDATION 5.2: We recommend the diagnosis of CID for patients with impairment (quantitative or functional) of both cellular and antibody immune functions.**

Strength of recommendation: **Strong**

Quality of evidence: **High.**

CID is characterized by abnormalities in both antibody and cell-mediated immunity. Monogenic disorders with significant T cell lymphopenia, although less severe than SCID, and leading to a CID phenotype, form a separate category within the IUIS classification of IEI, often having their own specific diagnostic laboratory approach in addition to genetic testing (**Table 5.1**). This testing is recommended in addition also to those referred to in **RECOMMENDATION 5.1** Confirmation of a specific underlying genetic cause and diagnosis may enable tailored therapy.

Hypomorphic pathogenic variants of SCID-associated genes may lead to “leaky” forms of SCID and may not always present in infancy. Clinical and immunological presentation is similar to CID, with increased risk of infection, autoimmunity and lymphoproliferative disease.<sup>253-255</sup>

**Table 5.1. Examples of specific laboratory testing for CIDs with or without syndromic features.**

IEI	Associated genes	Available clinical testing
Hyper IgM Syndrome	<i>CD40L, CD40, UNG, IKBKG, NFKBIA, ATM, NBS1, PMS2, MSH6, PIK3CD, PIK3RI</i>	CD40L surface expression and function (CD40-mulg) CD40 surface expression B cell subset phenotyping
MHC Class I deficiency	<i>TAP1, TAP2, TAPBP, B2M</i>	MHC Class I expression on multiple immune cell types, increased CD4:CD8 ratio
MHC Class II deficiency	<i>RFXANK, RFX5, RFXAP, CIITA</i>	MHC Class II expression on B cells and monocytes, inverted CD4:CD8 ratio
<b>CID with syndromic features</b>		
Wiskott Aldrich Syndrome	<i>WAS</i>	WASp expression in lymphocytes
DNA repair defects	<i>ATM, NBS1, BLM, DNMT3B, ZBTB24, PMS2, POLE1, POLE2, LIG4</i>	Serum AFP levels (>6 mo of age) Flow cytometry analysis of DNA repair
Immunodeficiency, centromeric instability and facial anomalies (ICF) syndrome	<i>DNMT3B, ZBTB24, CDCA7, HELLS</i>	Cytogenetic analysis for evaluation of centromeric instability
Thymic insufficiency with congenital/syndromic features	<i>Chr22q11.2 deletion, TBX1, TBX2, CHD7, FOXP1, PAX1</i> 11q23del, 10p13-p14 deletion	TREC levels or recent thymic emigrants by flow cytometry Chromosomal analysis (SNP array),
Hyper IgE Syndromes (HIES)	<i>STAT3, DOCK8, PGM3, CARD11, IL6R, IL6ST, ERBIN, and ZNF431</i>	Serum IgE, eosinophil count TH17 cells quantification DOCK8 expression
Cartilage Hair Hyperplasia	<i>RMRP</i>	Evaluation of compartment-specific telomere length.

Clinical features of selected CIDs are discussed below.

*Hyper IgM Syndromes present with low serum levels of IgG and IgA, and normal or elevated serum IgM levels.*

Monogenic IEI characterized by normal or elevated serum IgM levels and low serum levels of IgG, IgA, and IgE are collectively classified as Hyper IgM Syndromes (HIGM). The underlying pathology in HIGM is the inability to class-switch immunoglobulins thus resulting in normal or elevated levels of serum IgM and decreased levels of all other immunoglobulin isotypes. HIGM syndromes are caused by pathogenic variants in genes

involved in class-switch recombination (e.g., *CD40L*, *CD40*, *AID*)<sup>256-259</sup> (**also see RECOMMENDATION 4.8**) and others that are caused by impaired T-B cell interaction and activation signaling (*IKBKG*, *NFKBIA*, *ATM*, *NBS1*, *PMS2*, *MSH6*, *PIK3CD*, *PIK3RI*).<sup>260-262</sup> *CD40L* pathogenic variants account for approximately 70% of reported HIGM syndromes.<sup>256</sup>

The clinical presentation may vary depending on the underlying genetic cause and include susceptibility to recurrent bacterial and opportunistic infections, gastrointestinal and pulmonary complications, autoimmune cytopenias, inflammatory bowel disease, lymphoproliferation and malignancies.

Laboratory features of *CD40L* and *CD40* deficiency include low serum IgG levels with normal or elevated serum IgM, and low serum IgA levels. Specific antigen antibody production is impaired. Peripheral blood T, B and NK cell quantification is generally normal, however, memory B cells, specifically class-switched memory B cells (CD27+IgD-IgM-), are significantly decreased. Upregulation of *CD40L* on stimulated CD4+ T cells, measured by flow cytometry, is significantly low or absent in 80% of cases of XL-HIGM due to *CD40L* deficiency.<sup>257</sup> *CD40L* pathogenic variants that result in normal expression but non-functional *CD40L* are not detected with this method. A modification of the flow cytometry assay using the extracellular domain of *CD40* fused with murine IgG-Fc (*CD40*-mulg) enables functional analysis of *CD40L* and can identify all cases of *CD40L* deficiency.<sup>258</sup> Female carriers of *CD40L* deficiency with extreme skewing of lyonization of the X-chromosome may be clinically symptomatic.<sup>259</sup> B cells from patients with AR-HIGM syndrome due to *CD40* null variants lack *CD40* expression, which can be demonstrated by flow cytometry.<sup>260</sup> Abnormal test results for *CD40L* and/or *CD40* analysis are confirmed with genetic analysis of *CD40L*.

*MHC Class I and II deficiencies present with abnormal CD4:CD8 ratio, or significant CD8 T cell lymphopenia, or CD4 T cell lymphopenia and severe, recurrent infections*

MHC Class I and II deficiencies are rare, autosomal recessive CIDs.<sup>261</sup> As interaction with MHC class I and class II in the thymus is crucial for development of CD8 and CD4 T cells, respectively, pathogenic variants of genes involved in peptide loading and transport (*TAP1*, *TAP2*, *TAPBP*) or assembly of MHC class I on the cell surface (*B2M*) result in decreased or absent MHC Class I surface expression and consequently significantly low or absent CD8 T cells.<sup>261</sup> Similarly, pathogenic variants of genes that control MHC Class II gene expression (*RFXANK*, *RFX5*, *RFXAP*, *CIITA*) lead to decreased surface MHC Class II expression and therefore low or absent CD4 T cells.<sup>262,</sup>

<sup>263</sup>

Flow cytometry analysis of peripheral blood for surface expression of MHC Class I (all nucleated cells) and MHC Class II (B cells and antigen-presenting cells) along with genetic analysis for the suspected gene defects is necessary to confirm the diagnosis.

**RECOMMENDATION 5.3: We recommend immunological investigations and testing of diagnostic biological markers in patients with suspicion of CID and certain clinical findings in non-immunological organs and systems (syndromic features).**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

CIDs with syndromic features form a distinct group of IEI. These patients are susceptible to bacterial, fungal, and/or viral infections and have distinctive non-immunologic features. Patients with syndromic CIDs should undergo targeted immunologic testing when available, in addition to investigation of cellular and humoral immunological compartments (**Table 5.1**).

Wiskott Aldrich Syndrome (WAS) and related disorders present with thrombocytopenia, eczema and increased susceptibility to infection

Wiskott Aldrich Syndrome (WAS) is an X-linked syndromic CID that occurs due to pathogenic variants in *WAS*, resulting in lack of expression or non-functional WAS protein, and pronounced deficits in multiple hematopoietic cell lineages.<sup>264</sup> WAS patients present with micro-thrombocytopenia, bleeding diathesis, eczema, severe and recurrent infections, autoimmune disease, and EBV-associated B cell lymphoma.<sup>265</sup> Allelic variants of WAS include X-linked thrombocytopenia (XLT), which is associated with hypomorphic loss-of-function (LOF) variants,<sup>266, 267</sup> and X-linked neutropenia and myelodysplasia, associated with gain-of-function (GOF) variants).<sup>268, 269</sup>

Laboratory findings in WAS patients include thrombocytopenia with small platelet size, abnormal immunoglobulin levels, and defective antibody responses to specific antigens. T cell numbers are decreased. T cell proliferation in response to anti-CD3 stimulation is significantly low and normalizes with the addition of IL-2.<sup>270</sup> Other immunological abnormalities include impaired chemotaxis of neutrophils and impaired cytotoxicity of NK cells, decreased Treg function, and increased autoreactive B cells. Flow cytometry analysis for intracellular WASP and genetic testing are necessary for confirmation of diagnosis, as WASP is not decreased in all cases.<sup>271</sup> Extreme lyonization of the abnormal X-chromosome in female carriers may result in clinical manifestations of WAS.<sup>272-274</sup>

Biallelic pathogenic variants of *WIPF1*, which encodes WASP interacting protein (WIP) that stabilizes WASP, result in a clinical phenotype resembling WAS.<sup>275</sup>

Defects of DNA repair present with frequent infections in combination with neurological deficits, growth retardation, skeletal, and immunological abnormalities.

DNA repair deficiencies are characterized by cutaneous, neurological, and immunological abnormalities. DNA repair deficiencies occur due to pathogenic variants

of *ATM*, *NBS1*, *BLM*, *DNMT3B*, *ZBTB24*, *PMS2*, *POLE1*, *POLE2*, and *LIG4* (and other less frequently encountered genes). Additional clinical features in these patients include frequent infections, skeletal abnormalities, growth retardation, and increased risk of malignancy.<sup>276</sup>

Clinical features of ataxia telangiectasia (A-T, due to pathogenic variants in *ATM*), include cerebellar ataxia, oculocutaneous telangiectasias, growth retardation, increased risk of malignancy and variable immune deficiency.<sup>277, 278</sup> Elevated serum alpha fetal protein (AFP) level is a consistent laboratory finding in A-T patients over 6 months of age.<sup>279</sup> Other findings are T cell lymphopenia and low TREC levels at birth (**see Section 2**), an increase of gamma-delta T cells, impaired T cell proliferative responses, low serum IgG, IgA, and IgE levels with normal or elevated IgM, and impaired antibody responses to specific antigens. HIGM is among the differential diagnoses given the serum immunoglobulin abnormalities in A-T.<sup>277</sup>

Similar immunological findings are seen in other DNA repair syndromes such as *NBN* deficiency and *LIG4* deficiency, therefore genetic sequencing is recommended to confirm the specific genetic defect.

Laboratory evaluation for lymphocyte radiosensitivity is recommended to complement immune and genetic assessment of patients with suspected DNA repair defects.<sup>280</sup> The assay involves measurement of phosphorylation of key proteins (*ATM*, *SMC1* and *H2AX*) in the non-homologous end joining (NHEJ) and of double-stranded DNA (DNA DSB) breaks after exposure of cells to low-doses of ionizing radiation, with assessment of the temporal course of DNA repair.<sup>281</sup> The pattern of initiation and repair of the DNA DSB pathway is associated with the diagnosis (e.g., *ATM*, *NBN* with defects in DNA DSB damage response initiation vs. radiosensitive SCID, e.g., *DCLRE1C*, *LIG4*, *NHEJ1*, which are associated with defects in the DNA DSB repair process). Some of these defects may also be associated with increased cell apoptosis and/or cell death after exposure to radiation, which is also measured in this flow cytometry assay.

*Developmental delay, abnormal facies (low-set ears, hypertelorism, epicanthal folds, and flat nasal bridge) are features for the diagnosis of Immunodeficiency, centromeric instability and facial anomalies (ICF) syndromes.*

Patients present with abnormal facies, congenital malformations including inguinal hernia and hypospadias, cleft palate, syndactyly, and cardiac defects. Chromosomal methylation is defective in these patients. Approximately 50% of ICF patients have pathogenic variants in *DNMT3B* (ICF1), less frequent in *ZBTB24* (ICF2), *CDCA7* (ICF3), and *HELLS* (ICF4), while some patients with an ICF phenotype have no identified genetic cause.<sup>282</sup>

Immunological laboratory findings include hypogammaglobulinemia or agammaglobulinemia, variable T and B cell absolute numbers ranging from low to normal, and low T cell proliferative responses. Cytogenetic analysis for the evaluation of

centromeric instability may demonstrate breaks, deletions, multibranched configurations, and interchanges between homologous and non-homologous chromosomes, frequently involving chromosomes 1, 16 and 9, and rarely 2 and 10.<sup>283</sup>

*DiGeorge Syndrome (DGS) present with congenital conotruncal heart disease, thymic aplasia or hypoplastic thymus, hypoparathyroidism, and midline craniofacial defects.*

The underlying genetic etiology of most DGS patients is heterozygosity for Chr22q11.2 deletion (~90% of DGS patients, 1 in 4000 live births).<sup>284</sup> In contrast, Chr22q11.2 deletion accounts for only 38% of congenital athymia cases treated with cultured thymus tissue.

Severity of immunodeficiency in DGS patients varies depending on the degree of lymphopenia with approximately 1% or less of Chr22q11 deletion syndrome patients presenting with athymia and a SCID-like phenotype (**See Section 2**).<sup>285</sup> Clinical features of the syndrome might not be present in all patients. Laboratory findings in thymic insufficiency are T cell lymphopenia and low TRECs, which when severe may be identified by an abnormal newborn screen for SCID. Expanded memory T cells may be detected in cases of severe lymphopenia due to engraftment of maternal T cells or oligoclonal expansion of autologous self-reactive T cells (**See Section 2**). B cell numbers may be normal or low, and serum immunoglobulin levels can be variable with defective antibody responses to pneumococcal polysaccharide vaccine. Testing for copy number variants and gene sequencing analysis is essential for diagnostic confirmation.

Other genetic causes of thymic insufficiency with associated congenital anomalies include pathogenic variants of *TBX1* and *TBX2*, pathogenic variants of *CHD7* resulting in CHARGE syndrome (Coloboma, Heart defects, Atresia, Retarded development, Genital and Ear anomalies), biallelic and monoallelic LOF variants of *FOXP1*, biallelic variants of *PAX1*. Non-genetic etiologies of congenital thymic insufficiency include diabetic embryopathy or maternal retinoic acid exposure during pregnancy.

*Hyper IgE Syndrome (HIES) presents with respiratory and skin infections, eczema and elevated serum IgE levels.*

Hyper IgE Syndromes (HIES) are characterized by recurrent sinopulmonary infections, eczematous dermatitis, eosinophilia, and elevated serum IgE.<sup>286</sup> Recurrent cutaneous infections with *Staphylococcus aureus* and *Candida albicans* are frequent. Several gene defects cause HIES.<sup>287</sup> The most frequent presentation is AD-HIES due to pathogenic LOF variants of *STAT3* (Job's syndrome). Additional clinical features in *STAT3* deficiency include increased risk of infections with fungi, non-tuberculous mycobacteria (NTM), development of bronchiectasis and pneumatocoles, osteoporosis, coarse facies, delayed shedding of primary teeth, and hyperextensible joints. *DOCK8* deficiency, presenting as AR-HIES, is associated with disseminated cutaneous viral infections, commonly due to HSV, HPV or severe *molluscum contagiosum*. These patients may

also present with autoimmune vasculopathies and neurological involvement. Other genetic causes of HIES include pathogenic variants of *PGM3*, *CARD11*, *IL6R*, *IL6ST*, *ERBIN*, and *ZNF431*.<sup>287</sup> *STK4* deficiency present with polyclonal hypergammaglobulinemia, which includes elevated IgE.<sup>288</sup>

Significantly elevated serum IgE levels with variably low or normal levels of other immunoglobulin isotypes and impaired specific antibody responses are characteristics of HIES. *STAT3* deficiency is associated with low numbers of Th17 and Tfh cells,<sup>289</sup> increased Tregs, and decreased memory B cells. *DOCK8* deficiency presents with T cell lymphopenia in addition to HIES. Flow cytometry for intracellular *DOCK8* expression is helpful for confirmation of diagnosis.<sup>290, 291</sup>

*Cartilage Hair Hyperplasia (CHH), an immuno-osseous dysplasia, presents with short limbs, short stature, fine sparse hair, and immunodeficiency.*

CHH, caused by biallelic pathogenic variants in *RMRP*, is a syndromic CID characterized by short stature, fine, sparse hair, immunodeficiency, Hirschsprung disease, and increased susceptibility to hematologic malignancies, particularly non-Hodgkin lymphoma and basal cell carcinoma.<sup>292-294</sup> CHH is also associated with autoimmune complications. While rare in the general population, CHH has a reported incidence of 1 in 1340 live births in the Amish population and 1 in 23,000 live births in the Finnish population,<sup>295</sup> explained by the presence of founder mutations in these populations. Depending on the severity of T cell lymphopenia, newborns with CHH may have an abnormal newborn screen for SCID (**See Section 2**).

Laboratory testing in CHH may reveal multiple immunologic abnormalities including hypogammaglobulinemia, neutropenia, lymphopenia, particularly T cell lymphopenia, and defective T cell proliferative responses.<sup>296</sup> Shortened telomeres in T and NK cells are diagnostic of CHH when clinical features are suggestive of the syndrome and should be included in the laboratory workup.<sup>297, 298</sup> Telomere length is measured in various leukocyte populations by Flow-FISH technology.<sup>299, 300</sup>

*Calcium channel defects present with anhidrotic ectodermal dysplasia, muscular hypotonia, and severe immunodeficiency.*

Calcium signals play a key role in activation and function of lymphocytes. Defects of  $\text{Ca}^{2+}$  influx from extracellular spaces into lymphocytes through the Calcium Release-Activated Calcium (CRAC) channels, result in severe congenital immunodeficiency. This has been shown in patients with biallelic pathogenic variants of *ORAI1*, *STIM1*, and *CRACR2A*.<sup>301</sup>

Calcium channel defects result in a clinical phenotype characterized by anhidrotic ectodermal dysplasia, muscular hypotonia, and severe T and B cell immunodeficiency. T cell and B cell numbers may be normal, but T cell proliferative responses to mitogen

stimulation are significantly decreased. Patients with *STIM1* pathogenic variants may also present with low Treg numbers, autoimmunity and lymphoproliferation.

**RECOMMENDATION 5.4: We suggest periodic assessments of immunological function in patients with CID and syndromic features.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Low**

As the immune phenotype and associated complications may evolve with age, it is important to perform periodic immune evaluations for patients with CIDs, every six months or more frequently, as determined by the complexity and severity of the CID. Evolving autoimmune complications, progressive lymphopenia, hematological malignancies, or organ-specific disease are documented complications in various CIDs. Thus, establishing a baseline immune phenotype and function at the time of initial evaluation with periodic evaluation for changes in immune phenotype or function is useful for optimal clinical management. (**Sections 8-12**).

**Neutrophil defects.**

**RECOMMENDATION 5.5: We recommend that patients with suspected quantitative neutrophil defects be screened with serial CBCs with differential.**

Strength of recommendation: **Strong**

Certainty of evidence: **High.**

Common infections in neutropenic patients include pharyngitis with lymphadenopathy, pneumonia, mastoiditis, and cellulitis. Patients may also experience oral ulceration, gingivitis, and mucosal ulcers in the vaginal or rectal area.<sup>302</sup> The severity of infections correlates with the severity of neutropenia.<sup>303</sup>

Severe congenital neutropenia (SCN) can be cyclic or persistent and is associated with pathogenic variants of genes involved in neutrophil development: SCN1 (*ELANE*), SCN2 (*GFI1*), SCN3 (*HAX1*), SCN4 (*G6PC3*), and SCN5 (*VPS45*). (**Table 5.2**) Wiskott Aldrich Syndrome (WAS) variant X-linked neutropenia should also be considered, particularly if neutropenia is associated with increased bleeding tendency (**See RECOMMENDATION 5.3**).<sup>304, 305</sup>

Serial CBCd measurements may be performed up to 2-3 times weekly for 6-8 weeks to identify cyclic from persistent or chronic neutropenia. Cyclic neutropenia usually follows a periodicity of about 21 days, but it can range from 14 to 36 days.<sup>303, 304</sup> Infections occur during the nadirs of neutrophil count, but there may be a delay between nadirs and the onset of symptoms. Neutrophil morphology is useful for the differential

diagnosis of neutropenia (e.g., giant cytoplasmic granules within neutrophils may be indicative of Chediak-Higashi Syndrome (*LYST*)). Persistent neutrophilia suggests leukocyte adhesion deficiency (**RECOMMENDATION 5.6**)

The bone marrow aspirate in SCN due to pathogenic variants of *ELANE*, *HAX1*, *WAS*, *G6PC3*, and *G-CSFR* typically reveals hypocellularity with early myeloid arrest, whereas hypocellularity with decreased myeloid precursors is seen in SCN due to Schwachman-Diamond Syndrome, GSD1b, WHIM syndrome (Warts, Hypogammaglobulinemia, recurrent bacterial Infections and Myelokathexis) (*CXCR4*-GOF), Cohen syndrome, and Hermansky-Pudlak syndrome.

**Table 5.2. Defects of neutrophil numbers and function**

Neutrophil defect	Genes associated	Recommended laboratory testing
Congenital neutropenia	<i>ELANE</i> , <i>HAX1</i> , <i>WAS</i> , <i>G6PC3</i> , <i>SLC37A4</i> , <i>TAZ</i> , <i>VPS13B</i> , <i>JAGN1</i> , <i>CSF3R</i> , <i>CEBPE</i> , <i>SMARCD2</i> , <i>HYOU1</i> , <i>SBDS</i> , <i>DNAJC21</i> , <i>EFL1</i> , <i>USB1</i> , <i>SRP54</i> , <i>CXCR2</i> , <i>WAS</i>	Serial CBC with differential Bone marrow aspirate
Leukocyte Adhesion Defect I	<i>ITGB2</i> (AR)	Flow cytometry to assess CD18
Leukocyte Adhesion Defect II	<i>SLC35C1</i> (AR)	Flow cytometry to evaluate sialyl Lewis X (CD15s) expression on leukocytes.
Leukocyte Adhesion Defect III	<i>FERMT3</i> (AR)	Platelet function
Leukocyte Adhesion Defect IV	<i>RAC2</i> (AR)	Assessment of neutrophil chemotaxis DHR with fMLP for oxidative burst assessment
XL-Chronic Granulomatous Disease	<i>CYBB</i>	DHR test for neutrophil oxidative burst
AR-Chronic Granulomatous Disease	<i>CYBA</i> , <i>CYBC1</i> , <i>NCF1</i> , <i>NCF2</i> and <i>NCF4</i>	DHR test for neutrophil oxidative burst Flow cytometry for individual NADPH oxidase complex proteins
Pulmonary Alveolar Proteinosis	<i>CSF2RA</i> , <i>GATA2</i>	Analysis of anti-GM-CSF autoantibodies

\*DHR, dihydrorhodamine oxidation assay; XL, X-linked; AR, autosomal recessive

**RECOMMENDATION 5.6: We recommend that patients with suspected leukocyte adhesion deficiency (LAD) be tested with flow cytometry analysis of relevant phagocyte surface molecules for LAD I and II and targeted genetic testing for LAD I, II, III and IV.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Leukocyte adhesion deficiency (LAD) can present as distinct types: LAD-I, LAD-II, LAD-III, and LAD-IV, each associated with different gene defects and distinct clinical features (**Table 5.2**). LAD should be suspected in patients with recurrent cellulitis, severe gingivitis, chronic abscesses, or respiratory tract infections along with increased white blood cell counts, mimicking myeloid leukemia or leukemoid reactions.<sup>306, 307</sup>

LAD-I (CD18 deficiency) patients experience severe infectious complications early in life, with omphalitis and delayed (over 3 weeks of age) umbilical cord separation. In milder cases, infections are limited to impaired wound healing with reduced pus formation at wound sites and severe periodontitis.<sup>308</sup> LAD-II (SLC35c1 deficiency) patients present with pulmonary infections, chronic severe periodontitis, growth and developmental delay, and a unique facial appearance.<sup>307</sup> LAD-III (kindlin 3 deficiency) patients exhibit dysfunctional platelet aggregation, leading to bleeding complications, similar to Glanzmann thrombasthenia, including cerebral hemorrhage at birth.<sup>306, 307</sup> LAD-IV (Rac2 deficiency) patients present with delayed umbilical cord separation, recurrent infections and impaired wound healing.<sup>309</sup>

A baseline elevated complete blood cell count (CBC) with differential is the first diagnostic finding.<sup>306, 306</sup> Flow cytometry supports a diagnosis of LAD-I/II: LAD-I is characterized by the absence or reduced expression of CD18 on the surface of neutrophils and monocytes. LAD-II is identified by the absence of sialyl Lewis-X/CD15s on myeloid cells, and Bombay (hh) blood group. LAD-III diagnosis relies on demonstrating impaired platelet function and requires genetic analysis for pathogenic variants in *FERMT3*.<sup>307</sup> LAD-IV patients have decreased neutrophil chemotaxis and normal neutrophil oxidative burst when stimulated with phorbol myristate acetate (PMA) but diminished oxidative burst when stimulated with fMLP, a physiological activator of neutrophils.<sup>309, 310</sup>

**RECOMMENDATION 5.7: We recommend that patients with suspected chronic granulomatous disease (CGD) have measurement of phagocyte oxidase activity and genetic testing for CGD-associated gene defects.**

Strength of recommendation: **Strong**

Certainty of evidence: **High.**

CGD should be suspected in patients with deep-seated infections with bacteria and fungi, particularly *Pseudomonas spp*, *Serratia spp* and *Aspergillus spp*, regardless of age of onset.<sup>311</sup> CGD should also be suspected in patients with very-early onset inflammatory bowel disease, which presents before age 6 years.<sup>312</sup> Pathogenic variants of *CYBB* cause X-linked CGD and biallelic pathogenic variants of *CYBA*, *CYBC1*, *NCF1*, *NCF2* and *NCF4* cause autosomal recessive (AR) CGD.

The initial screening test for CGD is the measurement of phagocyte oxidase activity, preferably using the dihydrorhodamine 123 (DHR) oxidative burst assay rather than the nitroblue tetrazolium (NBT) reduction assay.<sup>313</sup> The DHR assay, a flow cytometric assay, is objective and quantitative, whereas the NBT assay provides a microscopic visual readout, which is qualitative and subjective with higher false-negative results and a lower ability to detect AR forms of CGD. It is important to consider that the neutrophil oxidative burst test results may be compromised if time from sample collection to testing is prolonged over 24 hrs, due to spontaneous neutrophil degranulation.<sup>314</sup> Neutrophil oxidative burst test is reported as a Stimulation Index (SI), which represents the increase in oxidative burst activity following *in vitro* stimulation of the patient sample. Neutrophils from patients with X-linked CGD show little to absent oxidative burst activity (i.e., SI is 1), whereas neutrophils from patients with AR-CGD may have marginal to moderate oxidative burst activity. Female carriers of X-linked CGD have a population of neutrophils with normal oxidative burst and a population with little to no oxidative burst. Rarely, female carriers of XL-CGD may present with severe infections typical of XL-CGD when their neutrophils are heavily skewed towards the abnormal population.<sup>134</sup> About one-third of female carriers may also present with autoimmune manifestations.<sup>315</sup>

While decreased oxidative burst is typical of CGD patients, neutrophil oxidative burst may be decreased in other monogenic defects including *MPO* deficiency,<sup>316</sup> *G6PD* deficiency,<sup>317</sup> *RAC2* deficiency,<sup>309</sup> Protein kinase C  $\delta$  deficiency<sup>318</sup> and *GSD1b* deficiency.<sup>319</sup>

Gene testing provides ultimate confirmation and may be performed concurrently with analysis of neutrophil oxidative burst when clinical findings and/or family history are strongly suggestive of a neutrophil defect. (**See Section 3**) Analysis of *NCF1* is not commonly included in CGD targeted gene panels due to sequencing difficulties posed by presence of pseudogenes.<sup>311</sup> Flow cytometry for detection of specific NADPH oxidase complex proteins may help to rapidly diagnose CGD genetic subtypes and identify patients with *NCF1* variants that may be missed on exome or targeted gene panels.<sup>313, 320</sup>

**RECOMMENDATION 5.8: We recommend that patients with pulmonary alveolar proteinosis (PAP) be tested for pathogenic variants in the genes encoding the GM-CSF receptor and for autoantibodies to GM-CSF.**

Strength of recommendations: **Strong**

Certainty of evidence: **High.**

PAP is a rare and progressive chronic lung disease caused by defective alveolar macrophages needed for surfactant homeostasis.<sup>321, 322</sup> Patients with PAP exhibit increased risk for both common respiratory infections and opportunistic infections, which are primarily controlled by phagocytes in immunocompetent individuals. These include

1938 nontuberculous mycobacteria, as well as fungi such as *Aspergillus*, *Cryptococcus*,  
1939 *Histoplasma*, *Nocardia*, and *Proteus* species, causing infections in the lungs, central  
1940 nervous system, joints, and disseminate throughout the body.<sup>323</sup>

1941 PAP is caused by defects in the GM-CSF receptor  $\alpha$  and  $\beta$  subunits or GATA2  
1942 haploinsufficiency or arise secondary to hematologic malignancy, immunosuppressive  
1943 medication use, or toxin inhalation.<sup>323, 324</sup> Most adult patients diagnosed with PAP do not  
1944 have a germline genetic defect; instead, they have neutralizing autoantibodies against  
1945 GM-CSF.<sup>325, 326</sup> Analysis of neutralizing autoantibodies to GM-CSF is recommended to  
1946 identify an underlying autoimmune cause of PAP.<sup>327</sup>

1947

#### 1948 **Defects of innate immunity.**

1949

1950 **RECOMMENDATION 5.9: We recommend that patients with suspected inherited**  
1951 **susceptibility to a specific pathogen(s) be investigated for associated gene**  
1952 **defects of innate immunity, in addition to exclusion of adaptive immune defects**  
1953 **and secondary causes of immune defects.**

1954 Strength of recommendation: **Strong**

1955 Certainty of evidence: **Moderate**

1956 Increased susceptibility to viruses particularly herpes simplex encephalitis (HSE)  
1957 outside of the neonatal period or severe/recurrent/sustained HSE, and to human  
1958 papilloma virus (HPV) including severe, or extensive, or therapy-resistant cutaneous  
1959 warts, and epidermodysplasia verruciformis (EV).

1960 IEI involving the toll-like receptor (TLR)3 or interferon (IFN) pathways<sup>328</sup> have been  
1961 associated with increased susceptibility to HSE. Approximately 5% of children with HSE  
1962 and with high rates of HSE recurrence due to viral reactivation might have TLR3  
1963 deficiency.<sup>329</sup> NK cell defects can be associated with recurrent HSE.<sup>330</sup> Several  
1964 monogenic disorders associated with HSE have broad susceptibility to infections, such  
1965 as mycobacterial infection in STAT1 deficiency.<sup>331</sup> **(See Table 5.3)** Diagnosis of these  
1966 monogenic disorders in patients with HSE is critical for prophylaxis, disease  
1967 surveillance, and genetic counseling. As many of these conditions have an AD  
1968 inheritance pattern, it is important to screen family members once the diagnosis is  
1969 established. Currently no clinical testing is available for TLR3 function and other defects  
1970 in the TLR3 pathway, and genetic testing is required for diagnosis of these conditions.

1971 Regarding IEI associated with HPV infection, the majority of WHIM syndrome due to  
1972 GOF *CXCR4* variants and more than half of GATA2 haploinsufficiency patients develop  
1973 warts following  $\alpha$ -HPV infection.<sup>332</sup> Biallelic LOF variants of EV-associated genes (*TMC6*  
1974 and *TMC8*) can be identified in about half of EV patients. AD and X-linked recessive

1975 forms of EV have also been reported. Approximately two-thirds of EV patients develop  
 1976 non-melanoma skin cancer.<sup>333</sup>

1977 Defects of the type I IFN pathway, including presence of neutralizing anti-type I IFN  
 1978 autoantibodies present with severe viral infections (including COVID-19 and  
 1979 disseminated infections with vaccine strains (e.g., measles, yellow fever)).

1980 Approximately 15-20% of adults with severe COVID-19 pneumonia had deficiencies of  
 1981 type I IFN immunity due to either presence of neutralizing autoantibodies against type I  
 1982 IFN, or pathogenic variants of genes involved in type I IFN immunity.<sup>334</sup> Patients with  
 1983 autosomal recessive complete or partial LOF pathogenic variants in *STAT1* have  
 1984 increased susceptibility to broad types of viral illnesses and mycobacterial disease,  
 1985 while patients with heterozygous LOF variants in *STAT1* exhibit increased susceptibility  
 1986 to mycobacterial infection, and not to viral infections.<sup>335</sup> Patients with type I IFN defects  
 1987 including *STAT2* deficiency have increased risk of disseminated infections with live-  
 1988 attenuated viral vaccine strains.<sup>336</sup>

1989 Congenital asplenia may present with a family history of asplenia or sepsis caused by  
 1990 encapsulated bacteria, most frequently *S. pneumoniae*.

1991 Abdominal imaging to evaluate spleen anatomy and the assessment of pitted red cell  
 1992 count on peripheral blood are common diagnostic tests. There is not an established  
 1993 method to accurately assess splenic function.<sup>337, 338</sup> IgM memory B cells are depleted in  
 1994 asplenia patients. Blood smear for Howell-Jolly bodies is sensitive to detect moderate to  
 1995 severe hyposplenic function. Scintigraphy using <sup>99m</sup>Techetium labeled heat-damaged  
 1996 erythrocytes is used to assess spleen clearance of abnormal erythrocytes.

1997 Toll-like receptor (TLR) deficiencies present with recurrent serious infections with gram-  
 1998 positive bacteria.

1999 Patients with deficiencies in the TLR pathways have normal levels of immunoglobulins  
 2000 and vaccine antibody titers, normal complement, and normal phagocytic capacity. They  
 2001 might not have signs of inflammation despite active infection. Infections in TLR, IRAK4  
 2002 or MyD88 deficiency are limited to pyogenic bacteria in the form of sepsis, abscesses,  
 2003 cellulitis, arthritis, osteomyelitis, and meningitis. Patients with IKBKG and IKBA  
 2004 deficiencies have increased susceptibility to pyogenic bacteria, mycobacteria, viruses,  
 2005 fungi and parasites. Defects of TLR signaling are diagnosed by demonstrating  
 2006 decreases of TLR responses *in vitro*<sup>339</sup> and genetic defects of relevant genes. TLR3  
 2007 deficiency is singular for its association with HSV encephalitis.

2008 Chronic mucocutaneous candidiasis (CMC) presents with recurrent *Candida* species  
 2009 infection of the nails, skin, and mucous membranes.

2010 The laboratory testing for suspected CMC should include evaluation of NK cell  
 2011 numbers, T cell responses to *C. albicans*, Th17 cells,<sup>340</sup> IFN- $\gamma$  responses, and genetic  
 2012 analysis of relevant genes (*STAT1*, *AIRE*, *RORC*, *ACT1*, *CARD9* and genes encoding  
 2013 proteins of the IL-17 pathway).

2014 The presence of neutralizing autoantibodies to Th17-related cytokines in APECED  
 2015 patients<sup>341</sup> and dysregulation of INF- $\gamma$  responses.<sup>342</sup> are associated with CMC. CMC  
 2016 was reported in siblings associated with a homozygous LOF variant of *Dectin1*, however  
 2017 pathogenicity remains uncertain because this variant allele is common in the reported  
 2018 population.<sup>343</sup>

2019 Mendelian Susceptibility to Mycobacterial Disease (MSMD) present with severe  
 2020 tuberculous or atypical mycobacterial infections, Salmonella species infections, or  
 2021 herpesvirus infections, and normal results on screening studies of humoral and cellular  
 2022 adaptive immunity

2023 The clinical penetrance and severity of MSMD depend on genetic etiology and increase  
 2024 with decreasing level of IFN- $\gamma$  activity.<sup>344</sup> AD partial IFNGR1 deficiency presents in  
 2025 childhood later with more localized infections than AR IFNGR deficiency,<sup>345</sup> and typically  
 2026 presents with mycobacterial osteomyelitis. IL12B and IL12RB1 deficiencies have  
 2027 variable penetrance, which might be related to degree of pathogen exposure.<sup>345</sup>  
 2028 Patients with anti-IFN  $\gamma$  autoantibodies also present with increased susceptibility to  
 2029 mycobacterial infections and have been reported mostly in Southeast and East Asian  
 2030 countries.<sup>346, 347</sup>

2031 Testing for MSMD includes measuring STAT4 phosphorylation and IL12 secretion in  
 2032 lymphocytes stimulated with IL12, STAT1 phosphorylation induced by IFN- $\gamma$  , and cell  
 2033 surface expression of IFN- $\gamma$ R1 and IL12 $\beta$ R.<sup>345</sup>

2034 **Table 5.3: Examples of diagnostic assays for defects of innate immune system**  
 2035 **based on infection susceptibility. (Complement defects not included)**

Infection susceptibility	Genes associated	Recommended diagnostic assays other than genetic testing
HSV encephalitis	TLR3; UNC93B1; STAT1; IKBKG; IFNAR1; DOCK8	MSMD testing for IFNAR1, IFNAR2, or STAT1 deficiency
		Phenotyping and functional assessments of NK cells
		Toll-like receptor (TLR) assay
		Flow cytometric evaluation of IFN- $\gamma$ R (CD119) surface expression
		Flow cytometry for DOCK8 protein expression

<b>HPV</b> <b>Alpha-HPV</b> (muco-cutaneous warts and HPV-related cancers) <b>Beta-HPV</b> (epidermody splasia verruciformis EV)	<b>Alpha-HPV</b> <i>CXCR4</i> ; <i>DOCK8</i> ; <i>GATA2</i>  <b>Beta-HPV</b> <i>TMC6 (EVER1)</i> <i>TMC8 (EVER2)</i> <i>STK4</i> ; <i>RHOH</i> ; <i>MST1</i> ; <i>CORO1A</i>	Phenotyping and functional assessments of NK cells
Severe viral infections	<i>IKBKG</i> ; <i>TLR3</i> ; <i>GATA2</i> ; <i>STAT1</i> ; <i>TYK2</i> ; <i>IFNAR1</i> ; <i>IRF8</i> ; <i>IRF7</i> ; <i>IRF9</i> ; <i>MDA5</i> ; <i>ZNFX1</i> .	Phenotyping and functional assessments of NK cells  Targeted cytokine assays Autoantibodies to type 1 IFNs
Disseminated vaccine-strain measles and/or yellow fever	<i>IFNAR1</i> ; <i>IFNAR2</i> ; <i>TYK2</i> ; <i>STAT1</i> ; <i>STAT2</i> ; <i>IRF9</i> ; <i>IKBKG</i>	Phenotyping and functional assessments of NK cells  Targeted cytokine assays
Recurrent invasive pyogenic bacterial infection	<i>IRAK4</i> ; <i>MYD88</i> ; <i>IKBKG</i> ; <i>NFKBIA</i>	TLR-4 response to LPS
	Hypo/asplenia (for encapsulated bacteria)	Peripheral blood erythrocytes for pitted red cell count and/or IgM memory B cell count for hyposplenism  Blood smear for Howell-Jolly bodies  Abdominal imaging for asplenia.  Scintigraphy with <sup>99m</sup> Tc Technetium labeled heat-damaged erythrocytes
Chronic muco-cutaneous candidiasis	<i>AIRE</i> ; <i>IL17RA</i> ; <i>IL17RC</i> ; <i>IL17F</i> ; <i>STAT3</i> ; <i>DOCK8</i> ; <i>STAT1</i> ; <i>CARD9</i>	Enumeration of Th17 cells by flow cytometry  Autoantibodies against IL-17A or IL17F for acquired CMC
Mycobacterial disease (MSMD)	<i>IFNGR1</i> ; <i>IFNGR2</i> ; <i>IKBKG</i> ; <i>IL12RB1</i> ; <i>IL12B1</i> ;	Targeted cytokine assays

	<i>IL12RB2; IL23R ; STAT1 ; JAK1; IFNG; GATA2</i>	Flow cytometry of IFNGR1 (CD119) and IL12RB1 (CD212) Autoantibodies against IFN-γ, for acquired MSMD

<https://cis.clinimmsoc.org/dli/test-directory.php>

### **Complement deficiency**

Inherited complement defects can result in recurrent infections, autoimmunity, and disorders related to complement hyperactivation. The latter includes thrombotic microangiopathies, renal disorders, age related macular degeneration and hereditary angioedema. (**Table 5.4**) Hereditary angioedema is not addressed in this practice parameter.

**RECOMMENDATION 5.10: We recommend that patients with recurrent or severe infections by encapsulated bacteria AND with normal antibody responses be evaluated for complement deficiency.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Patients with complement deficiencies have increased susceptibility to infection.<sup>348, 349</sup> Almost 50% are prone to bacteremia or severe infections such as pneumonia, meningitis, septicemia, or osteomyelitis, caused by encapsulated bacteria (e.g., *H. influenzae*, *N. meningitidis*, *S. pneumoniae*). Deficiency of the early components of the classical pathway also predisposes to autoimmune diseases such as systemic lupus erythematosus (SLE), juvenile rheumatoid arthritis, glomerulonephritis, Henoch-Schönlein purpura and dermatomyositis.<sup>350, 351</sup> C1s/C1r deficiencies are commonly inherited together. More than 50% of these patients and 90% of patients with deficiency of C1q are reported to have SLE or lupus-like syndrome. The leading cause of mortality in patients with C1q or C2 deficiencies experiencing infection or autoimmunity is complications related to their vascular system.<sup>352</sup> There is a 1% prevalence of non-functional C2 gene variants in the Caucasian population, and females with this deficiency have a higher risk of SLE.<sup>352</sup> C4 deficiency is rare and is strongly related to SLE.<sup>351</sup> Individuals with monoallelic pathogenic variants in C2 or C4 are asymptomatic.<sup>353</sup>

In addition to recurrent infections, patients with C3 deficiency can develop conditions such as membranous glomerulonephritis, SLE, atypical hemolytic uremic syndrome (aHUS) and age-related macular degeneration (AMD).<sup>353-355</sup>

2069 Deficiency in the components of the terminal pathway<sup>348, 353</sup> have increased risk of  
2070 meningococcal meningitis. Repeated *Neisseria* infections or family history of  
2071 meningococcal infections suggest terminal component deficiency.

2072 Patients with deficiency in the alternate pathway complement components such as  
2073 regulators Factor H, Factor I and properdin have also been reported to have severe  
2074 bacterial infections.<sup>6</sup> Properdin deficiency is an X-linked complement deficiency, which  
2075 presents with increased susceptibility to severe *Neisseria* infections including sepsis,  
2076 often during adolescence.<sup>356, 357</sup> Patients with Factor B and Factor D deficiencies have  
2077 been reported to have recurrent pneumococcal and meningococcal infections.<sup>358, 359</sup>

2078 Deficiency of lectin pathway components such as collectin and ficolin has not been  
2079 clearly associated with a clinical phenotype. Mannose binding lectin (MBL) deficiency is  
2080 observed in about 5-7% of Caucasian populations.<sup>360</sup> MBL deficiency has been reported  
2081 with increased susceptibility to meningococcal meningitis, human immunodeficiency  
2082 virus (HIV) infection, hepatitis C virus (HCV) infection and severe bacterial and fungal  
2083 infections producing sepsis. However, MBL deficiency is not a major risk factor for  
2084 infections by itself, and the severity of the infection may be due to the presence of other  
2085 immune system abnormalities.<sup>361</sup> MBL-associated serine protease 2 (MASP2)  
2086 insufficiency in combination with the anti-C1q autoantibody presence has been  
2087 associated with recurring pneumonia, pulmonary fibrosis, and ulcerative colitis<sup>361</sup> and  
2088 with febrile neutropenia in pediatric cancer patients.<sup>362</sup>

2089 Initial tests for evaluating complement function are CH50 and AH50, which help to  
2090 narrow down the specific affected complement component(s).<sup>353, 363-365</sup> Because  
2091 complement proteins are not stable, attention should be given to blood sample  
2092 collection and handling. Complement activation is temperature-dependent so serum  
2093 must be obtained from samples as soon as possible and stored at -80°C. If CH50 is low  
2094 with normal AH50 results, deficiencies in the classical pathway should be suspected; if  
2095 AH50 is low with normal CH50 results, it suggests a deficiency in the alternative  
2096 pathway. When both assays show low results, deficiency in the terminal pathway,  
2097 including regulatory proteins factors H and I, is likely. This approach should lead to  
2098 evaluation of specific pathway components.<sup>365</sup>

2099 Serum complement levels are maintained as a balance between production and  
2100 consumption through activation. Multiple complement components are decreased when  
2101 there is chronic over-activation of the pathway. Causes may include the presence of  
2102 autoantibody against a complement protein, deficiency in a complement control protein,  
2103 protein-losing enteropathies, chronic infection, or malnutrition.<sup>351, 366</sup> An increase in the  
2104 levels of activation fragments amidst multiple complement components helps distinguish  
2105 low results due to excessive consumption versus reduced production.<sup>366</sup> Measurement  
2106 of activation fragments also indicates the extent of involvement of the respective

pathways and the degree of inhibition when a patient is being treated with complement-targeted therapeutics.

**RECOMMENDATION 5.11: We recommend that patients presenting with thrombocytopenia, microangiopathic hemolytic anemia, and acute renal failure be screened for abnormalities of complement regulatory proteins and/or autoantibodies against complement Factor H (CFH) and related proteins 1 and 3 (CFHR1/CFHR3).**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Deficiency of complement regulatory proteins presents with recurrent infections, inflammatory disorders, protein-losing enteropathies, thrombotic microangiopathies or renal disorders, which include conditions such as age-related macular degeneration (AMD), atypical Hemolytic Uremic Syndrome (aHUS) and paroxysmal nocturnal hemoglobinuria (PNH).<sup>355, 367, 368</sup> aHUS is characterized by the triad of microangiopathic hemolytic anemia, thrombocytopenia, and acute kidney injury. The clinical findings of aHUS require exclusion of idiopathic thrombotic thrombocytopenic purpura (TTP), Shiga toxin-producing Escherichia coli (STEC) induced HUS, pregnancy related conditions and other causes of thrombotic microangiopathy.<sup>369</sup>

Deficiency of complement regulatory proteins in the kidney endothelium can result in uncontrolled amplification of the cascade, complement-mediated inflammation, secondary consumption of circulating complement factors, deposition of C3b on the kidney microvasculature and tissue injury,<sup>368</sup> leading to aHUS.<sup>369, 370</sup> About 20-30% of aHUS cases have pathogenic variants in Factor H, 5-10% in Factor I, 1-4% in Factor B, 10-15% in membrane cofactor protein (MCP)/CD46 and 3-5% have pathogenic variants in thrombomodulin.<sup>369, 371-373</sup> Ten percent of aHUS cases are due to autoantibodies against Factor H, and autoantibodies against complement Factor H-related proteins 1 and 3 have been reported (CFHR1/CFHR3).<sup>353, 374</sup>

GOF gene variants in C3 and C5 increase the stability of their respective convertases and similarly lead to aHUS.<sup>369, 370, 374</sup> Not all carriers of pathogenic variants in aHUS-associated complement genes show disease manifestations.<sup>375</sup>

C3 glomerulopathy (C3G) is also a rare kidney disease characterized by complement dysregulation of the alternative pathway due to mutations in Factor H, Factor I, and MCP.<sup>376</sup> C3G occurs in the fluid phase of the glomerular microenvironment causing C3 deposition and tissue injury. C3 nephritic factors, autoantibodies that bind to the C3 convertase, stabilizing and increase its half-life are, is seen in 50-80% of C3G cases. There have also been reports of C4 nephritic factors, which act through a similar mechanism on classical and lectin pathway C3 convertases in membranoproliferative

glomerulonephritis, meningitis, and sepsis.<sup>377</sup> In addition, presence of anti-Factor B antibodies has also been associated with C3G.<sup>377, 378</sup> Polymorphisms in genes encoding Factor H, Factor I, and C3 and dysregulation of the alternative pathway have also been associated with AMD, with retinal deposits of complement proteins and vision loss in elderly individuals.<sup>379, 380</sup> Decay accelerating factor (CD55) and CD59 are membrane-bound inhibitors that bind to anchoring structures encoded by the phosphatidylinositol glycan class A (PIG-A) gene to protect red blood cells. In Paroxysmal Nocturnal Hemoglobinuria (PNH), somatic mutations in *PIGA* leads to the premature death and impaired production of red blood cells.<sup>381</sup> Isolated CD55 deficiency has been associated with protein losing enteropathy,<sup>382</sup> and isolated CD59 deficiency has been associated with Guillain-Barré-like neurological symptoms.<sup>383</sup> Similarly, mutations in Factor H, MCP and Factor I have also been reported in conditions such as pre-eclampsia, hemolysis, elevated liver enzyme levels and low platelet levels (HELLP) syndrome, urinary infections, otitis, pyelonephritis, meningitis, and sepsis.<sup>384-386</sup>

**RECOMMENDATION 5.12: We recommend genetic testing when complement function is abnormal.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

When complement deficiency is suspected, genetic testing should be pursued in addition to protein level and functional assays.<sup>353, 386</sup> (**See Section 3**) Genetic polymorphisms of Factor H, CFHR1–5, C3 and rare variants of Factor I genes are associated with AMD or serve as risk predictors for AMD.<sup>388</sup> Disease specific targeted gene panels with specificity for complement-mediated TMA, aHUS, and C3G are now available.<sup>389</sup> Individuals' responses to complement-targeted therapeutics can vary in the context of their genetic background.<sup>390</sup> Genetic variants in C5 and rare polymorphisms of the complement receptor 1 gene may determine response to eculizumab therapy in PNH patients.<sup>390, 391</sup>

**Table 5.4 Complement Deficiencies and Associated Infection and Diseases**

Component	Infection	Other Diseases
<b>Classical Pathway</b>		
C1q, C1r and C1s, C2, C4	Encapsulated bacteria	SLE, Vasculitis, RA, SS, SSC Glomerulonephritis
<b>Lectin Pathway</b>		

MBL	Bacterial, fungal, protozoal, viral infections when with other immunological abnormalities	SLE, Inflammatory arthritis, cardiovascular
Ficolins (M, L, H)	Bacterial infections when with other immunological abnormalities	Pneumonia, Ulcerative colitis
MASPs	Bacterial infections when with other immunological abnormalities	Pneumonia, Pulmonary fibrosis, and Ulcerative colitis
<b>Alternate Pathway</b>		
Properdin, Factor B, Factor D	Meningococcus	aHUS, Glomerulonephritis
<b>Terminal Pathway</b>		
C3	Severe bacterial, Respiratory tract	Glomerulonephritis, SLE, RA, aHUS, AMD
C5, C6, C7, C8, C9	Meningococcus, Neisseria	SLE, glomerulonephritis Vasculitis, APS, Myasthenia Gravis, TMA
<b>Regulatory proteins</b>		
Factor H	Bacterial	ITP, aHUS, Glomerulonephritis, SLE, AMD
Factor I	Encapsulated Bacterial	aHUS, Glomerulonephritis, scleroderma, RA, Vasculitis
CD46		aHUS
CD59, CD55		PNH

SLE Systemic Lupus Erythematosus, RA Rheumatoid arthritis, SS Sjogren's syndrome, SSc Systemic sclerosis, ITP Immune thrombocytopenic purpura, aHUS Atypical Uremic Syndrome, PBC Primary Biliary Cholangitis, APS Antiphospholipid Syndrome, AMD Age-related macular degeneration, PNH Paroxysmal nocturnal hemoglobinuria; HAE, hereditary angioedema; AAE acquired angioedema.

## **Section 6. Immunologic diagnosis of immune dysregulation disorders (PIRD) and autoinflammatory disorders**

**RECOMMENDATION 6.1. We recommend evaluation for IEI in patients with clinical manifestations of immune dysregulation, such as immunodeficiency, autoimmunity, lymphoproliferation and autoinflammation.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Patients with manifestations of immune dysregulation should be evaluated for underlying genetic causes and for the presence of biomarkers of hyperinflammation, autoimmunity and immunodeficiency.<sup>8, 392</sup> Both humoral and cellular mechanisms are involved in immune dysregulation, including cytokines and chemokines, T and B cell subsets, NK cells, macrophages and the inflammasome.<sup>393, 394</sup>

Classification of immune dysregulation syndromes according to the type of response and the involvement of specific molecular and cellular mechanisms has been proposed. (See **Table 1.1- subtable IV**) Some of the common clinical presentations include cytokine release syndromes (CRS), hemophagocytic lymphohistiocytosis (HLH), systemic inflammatory response syndrome (SIRS), multisystem inflammatory syndrome related to COVID-19 in adults and children (MIS-A and MIS-C) and the interferonopathies. Classification can also be based on affected cellular phenotypes such as Treg cells, double negative T cells, T and B cell subsets, and innate immune cells such as macrophages and neutrophils.<sup>17</sup>

There is genetic predisposition to developing immune dysregulation.<sup>395-397</sup> While primary HLH is associated with pathogenic gene variants, there is also a genetic contribution that leads to increased risk of secondary HLH. Genetic defects in immune dysregulation disorders may involve germline or somatic variants, lyonization, mosaicism and epigenetic modifications. (**Section 3**)

**RECOMMENDATION 6.2. We recommend the assessment of cellular and humoral immunological function in patients with suspected immune dysregulation disorders.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

When evaluating suspecting immune dysregulation syndromes, it is important to be able to identify markers of inflammation. These include common non-specific markers such as ESR and CRP. Other markers include ferritin, triglycerides, fibrinogen, and clotting studies. Cytokine and chemokine serum levels may be useful in identifying the underlying mechanism of inflammation, such as distinguishing between an interleukin-1 mediated process versus an interferonopathy.<sup>398</sup> Examples of these tests are serum levels of IL-2Ra (soluble CD25) and CXCL9, which are elevated in IFN $\gamma$ -mediated inflammation. Immune dysregulation may present with abnormal lymphocyte sub-populations: regulatory T cells (Treg), Th17 cells, TCR $\alpha\beta$  DN T cells, follicular helper T cells (Tfh); B cell subsets (e.g., transitional B cells) and NK cells. (**see RECOMMENDATION 5.1**)

**RECOMMENDATION 6.3. We recommend that patients with periodic fevers and chronic systemic inflammation be evaluated for IEI and for secondary causes such as infection, autoimmune disease, or malignancy.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

An inflammatory condition is suspected when the patient presents with typical signs of inflammation: fever, pain, rashes and joint swelling.<sup>395-397</sup> Other signs can be present, including neurologic, gastrointestinal or pulmonary symptoms. A chronic inflammatory state may be suspected if the patient has recurrent or episodic symptoms, in addition to elevated C reactive protein and erythrocyte sedimentation rate in peripheral blood. Because of the variety of ways that inflammation can present, a high index of suspicion must be maintained. Diagnostic evaluation for both IEI and secondary causes should be performed in these chronic cases. The evaluation of autoinflammatory disorders requires a multidisciplinary approach with involvement of experts in Immunology and Rheumatology to differentiate clinical subtypes. Patients suspected of having an autoinflammatory disorder should undergo genetic testing early in the diagnostic process.

Autoinflammatory disorders are classified by the IUIS as: 1. Type I Interferonopathy; 2. Recurrent inflammatory syndromes, with or without skin findings; 3. Systemic inflammation predominantly in bone and joints; 4. Other systemic inflammatory syndromes. (Fig 7 in Bousfiha et al, 2022<sup>17</sup>).

#### Cryopyrin related disorders

Cryopyrin-associated periodic syndrome (CAPS) is suspected in patients presenting with episodes of systemic inflammation manifested by rash, fevers, arthritis, neurological deficits, hearing loss and amyloidosis.<sup>399</sup> Patients suspected of CAPS are screened for persistent systemic signs of inflammation in the absence of demonstrable infection, autoimmune disease, or malignancy. There is abnormal inflammasome activation with release of the pro-inflammatory cytokines IL-1 $\beta$  and IL-18. Patients presenting at or soon after birth with a pustular rash, joint swelling, and profound osteopenia and bone lesions may have deficiency of IL-1 receptor antagonist (DIRA). Patients presenting with generalized pustular psoriasis may have deficiency of IL-36 receptor antagonist (DITRA). Patients with phospholipase Cg2-associated antibody deficiency and immune dysregulation (PLAID) may present with atypical cold urticaria.

#### Periodic fever syndromes

Familial Mediterranean fever (FMF) or TNF receptor-associated periodic syndrome (TRAPS) present with recurrent and often prolonged fever attacks associated with serosal, cutaneous, and synovial manifestations.<sup>400</sup> Periodic fever with aphthous stomatitis, pharyngitis, and adenitis (PFAPA) should be suspected in young children

presenting with the namesake features and is a diagnosis of exclusion. Hyper-IgD syndrome (HIDS) presents fevers with lymphadenopathy, abdominal pain, diarrhea, vomiting, arthralgia, rash, aphthous ulcers, and splenomegaly. It represents a mild form of mevalonic kinase deficiency. Patients with suspected HIDS are screened by measuring serum IgD and urine mevalonic acid levels. Proteasome catalytic subunit b type 8 (*PSMB8*) and *TMEM173* defects are suspected in patients with early-onset fevers, systemic inflammation, and purpuric plaques caused by cutaneous leukocytoclastic vasculitis. Generalized pustular psoriasis and familial pityriasis rubra pilaris are present in patients with pathogenic variants in *CARD14*.

**RECOMMENDATION 6.4. We recommend that patients who exhibit lymphoproliferation and autoimmunity should be evaluated for IEI and for secondary causes, such as infection, autoimmune disease and malignancy.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Patients with immune dysregulation syndromes present with unexplained lymphoproliferation (defined as a pathologic accumulation of lymphocytes within secondary lymphoid organs and/or end-organs), autoimmune cytopenias (affecting at least two cell lineages), and other severe, recurrent or early onset autoimmunity. The evaluation of these conditions includes blood cell counts and auto-antibodies according to the tissue and organ affected.

The International Union of Immunological Societies (IUIS) classifies immune dysregulation into 4 broad phenotypes as follows: 1. Familial Hemophagocytic lymphohistiocytosis (HLH), with or without hypopigmentation, 2. disorders that confer Epstein-Barr Virus (EBV) susceptibility, including EBV associated HLH, 3. autoimmunity with or without lymphoproliferation including ALPS and Tregopathies, and 4. Immune dysregulation with colitis. (Fig 4 in Bousfiha et al, 2022<sup>17</sup>).

#### Familial HLH

The evaluation of HLH requires a multidisciplinary approach with involvement of experts in Immunology, Rheumatology, Infectious Disease and Hematology Oncology and Genetics and other services to differentiate subtypes of HLH.

Familial lymphohistiocytosis (FLH) is suspected in patients with fever, hepatosplenomegaly, and neurological symptoms. For primary HLH, testing should include perforin/granzyme by flow cytometry, and soluble CD25 levels. Secondary HLH can be triggered by malignancy, autoimmunity, infection, and iatrogenic causes. The underlying etiology of HLH may not be apparent in the disease's initial stages. The evaluation of suspected secondary HLH includes the diagnostic tools of primary HLH. Patients with IEI may develop HLH-like disease without meeting the HLH-2024

criteria.<sup>401</sup> These atypical forms of HLH should still be evaluated and treated as an immune dysregulation syndrome. These patients may need repeated and ongoing evaluation for humoral and cellular markers and genetic analysis to guide management. The diagnosis of FHL can be established if at least 1 of either 1, 2, or 3 below is fulfilled.

- 1) A molecular diagnosis consistent with FHL in a patient with signs/symptoms suggestive of HLH
- 2) Functional cellular findings consistent with FHL in a patient with signs/symptoms suggestive of HLH
- 3) Clinical diagnostic criteria for FHL with at least 5 of the 7 criteria below fulfilled\*
- 4) Fever  $\geq 38.5^{\circ}\text{C}$ 
  - a. splenomegaly ( $\geq 2$  cm below the costal margin)
  - b. cytopenias (affecting  $\geq 2/3$  lineages in the peripheral blood: hemoglobin  $< 90$  g/L; platelets  $< 100 \times 10^9/\text{L}$ ; neutrophils  $< 1.0 \times 10^9/\text{L}$  [in infants aged  $< 4$  wk: hemoglobin  $< 100$  g/L])
  - c. hypertriglyceridemia and/or hypofibrinogenemia:
  - d. fasting triglycerides  $\geq 3.0$  mmol/L and fibrinogen  $\leq 1.5$  g/L
  - e. hemophagocytosis
  - f. ferritin  $\geq 500$   $\mu\text{g/L}$
  - g. sCD25 (i.e., soluble interleukin-2 receptor)  $\geq 2400$  U/mL

### Tregopathies

Disorders in Treg cell function (called “Tregopathies”) often accompany IEI with other T cell subset abnormalities. This can lead to an autoimmune diathesis in which the balance of Treg cells with other T-cell types may dictate a concurrent immune deficiency with autoimmunity phenotype.<sup>157, 402</sup> A representative disorder in this group is IPEX.<sup>403</sup> In addition to Tregopathies, immune dysfunction leading to autoimmunity can occur through other immune mechanisms such as molecular mimicry, bystander activation, and cross-reactivity.

### Autoimmune lymphoproliferative syndromes (ALPS)

Chronic non-malignant lymphoproliferation, autoimmune cytopenias, and lymphoma are associated with autoimmune lymphoproliferative syndrome (ALPS),<sup>404, 405</sup> although many other IEI may present with an ALPS-like phenotype.<sup>405</sup> Patients with ALPS typically have elevated soluble FAS ligand (sFASL) and elevated serum levels of vitamin B12 and IL-10. Genetic testing may demonstrate pathogenic variants in *FAS*, associated with ALPS. ALPS and ALPS-like manifestations have recently been grouped into autoimmune lymphoproliferative immunodeficiency (ALPID) disorders, the most common of which include ALPS, CTLA-4 haploinsufficiency, LRBA deficiency, STAT3 gain of function (GOF) and activated phosphoinositide 3-kinase (PI3k) delta syndrome (APDS).<sup>406, 407</sup> ALPID disorders have increased double-negative T-cells (DNT), and other markers of immune dysregulation such as increased transitional B-cells, an atypical expansion of CD21<sup>lo</sup> B-cells, and decreased naïve CD4<sup>+</sup> T-cells.

### APECED (Autoimmune polyglandular syndromes)

Autoimmune polyendocrinopathy, candidiasis, ectodermal dystrophy (APECED), is one of the autoimmune polyglandular syndromes (APS), specifically APS-1. Clinical manifestations of APS-1 include hypoparathyroidism, Addison's disease and chronic mucocutaneous candidiasis (CMC).<sup>408</sup> APS-1 results from pathogenic variants in the Autoimmune Regulator (*AIRE*) gene. About 60 variants have been identified to cause APECED. Other clinical manifestations can occur, including associated with autoimmune involvement, such as type 1 diabetes mellitus, primary hypogonadism, and pituitary failure, etc. Diagnosis of APECED is made by identification of two or the 3 clinical components of APS1 or the presence of a pathogenic variant in the *AIRE* gene.

### Immune dysregulation with colitis

Colitis is a common feature of primary immune regulation disorders. There are several monogenic IEI associated with immune dysregulation and colitis presenting at an early age.<sup>409</sup> Inflammatory bowel diseases such as Crohn's disease or ulcerative colitis can accompany chronic granulomatous disease or adenosine deaminase (ADA) deficiency and may be manifestations of primary PIRDs. One mechanism involves loss of interleukin-10 (IL-10) or its receptor (IL-10R).<sup>410</sup> Clinical features may include diarrhea, abdominal pain, fever, weight loss or anemia or rectal bleeding. Severe cases may present with hemorrhage, perforation or toxic megacolon.

## **Section 7. Surveillance of potential clinical manifestations in IEI**

### **RECOMMENDATION 7.1: We suggest evaluation of growth (in Pediatrics) and nutritional status in patients with IEI.**

Strength of recommendation- **Conditional**

Certainty of evidence- **Moderate**

Patients with IEI are at risk for malnutrition,<sup>411-414</sup> and children with IEI are at risk for associated growth delay.<sup>414, 415</sup> Those with inflammatory or infectious gastrointestinal complications of IEI are especially at risk for nutritional deficiencies.<sup>416</sup> We recommend nutritional assessment every 6 to 12 months in patients with IEI and concerns for growth/nutritional deficiencies.

Height, weight, and BMI (percentiles for pediatric patients) should be reviewed at each visit to monitor for malnutrition or overnutrition and trends over time. Nutritional status may be monitored with serum albumin/prealbumin and additional micronutrient testing.

Referral to a dietitian for patients with IEI and weight/nutritional abnormalities, especially in those with immune-mediated or chronic infectious enteropathy, is helpful for providing and accessing optimal dietary intake.

**RECOMMENDATION 7.2: We suggest testing for specific pathogen infections in patients with IEI known to be associated with high morbidity and mortality to these infections.**

Strength of recommendation- **Conditional**

Certainty of evidence- **Moderate**

Surveillance and monitoring for viral infections, including EBV and CMV in blood should be performed periodically in patients with IEI susceptible to these viral infections, every three months or in the presence of symptoms. Adequate T and NK cell function is particularly important in controlling viral infections, thus deficiency and/or dysfunction in these cells confer high risk for recurrent or persistent viral infections, especially with EBV and CMV.<sup>417, 418</sup> (**Table 7.1**). Signs and symptoms concerning infection should guide the indications for infectious disease evaluation. PCR or antigen testing, rather than serology, is used in patients receiving immunoglobulin replacement therapy or those with impaired antibody responses. Patients with IEI have higher incidence, prolonged shedding, and higher recurrence rates of gastrointestinal infections than immunocompetent individuals, because of frequent antibiotic use, nutritional deficiencies, increased exposure to healthcare settings, and immunocompromised state. Patients with IEI who develop gastrointestinal symptoms should be screened for intestinal infections including *Clostridium difficile*, *Giardia lamblia*, *Cryptosporidium*, *Salmonella*, norovirus, and parasitic infections.<sup>419-421</sup> Gastrointestinal pathogen panel testing by PCR or antigen testing in stools should be considered when evaluating IEI patients. (**See Sections 9 and 10**)

**Table 7.1 – Examples of IEI associated with chronic viral infections and specific non-viral infections that may warrant evaluation or monitoring**

**RECOMMENDATION 7.3: We recommend the assessment of complete blood cell counts with differential in patients with IEI.**

Strength of recommendation- **Strong**

Certainty of evidence- **High**

Patients with antibody deficiencies and immune dysregulation disorders have a high incidence of autoimmune cytopenias, including ITP, AIHA, and AN, and hematologic malignancy (**Table 7.2**). While autoimmune cytopenias are typically an early finding in many of these IEI,<sup>431-434</sup> they can also develop after initial disease presentation. Therefore, close monitoring with complete blood cell counts with WBC differential (CBCd) to identify cytopenias or myelodysplasia at an early stage is appropriate. Routine CBCd should be checked every 3 to 12 months in patients with antibody

deficiencies and immune regulatory disorders to monitor for autoimmune cytopenias and myelodysplasia (as well as complications of Ig replacement therapy). Patients with longstanding IEI diagnosis and no cytopenias may require only annual testing (**See RECOMMENDATION 5.1**).

**Table 7.2 – Examples of IEI associated with autoimmune cytopenias**

IEI	Associated gene	Prevalence of autoimmune cytopenias	Reference
Common Variable Immunodeficiency (CVID)	Various (e.g., <i>NFKB1</i> , <i>NFKB2</i> )	10-18% prevalence ITP>AIHA>AN, First episode of immune cytopenia may occur before CVID diagnosis	435 151 153 436

RAS-associated Autoimmune Leukoproliferative Disorder (RALD)	<i>KRAS, NRAS</i> (somatic mutations)	94% prevalence Multilineage cytopenias>single lineage cytopenias	452

ITP, immune thrombocytopenia; AIHA, autoimmune hemolytic anemia; AN, autoimmune neutropenia

**RECOMMENDATION 7.4: We recommend *against* routine screening for autoantibodies, given the high proportion of asymptomatic patients with autoantibodies in circulation.**

Strength of recommendation- **Strong**

Certainty of evidence- **Moderate**

There is a growing list of IEI that are associated with increased rates of autoimmunity and immune-mediated pathology, especially in primary immune dysregulatory disorders where multiorgan autoimmunity is common.<sup>453, 454</sup> Additionally, non-specific autoantibodies have been identified in other acquired disease states, such as COVID-19 pneumonia, multisystem inflammatory syndrome in children, and Kawasaki's disease.<sup>455-457</sup> Broad autoantibody panels should not be ordered routinely. Instead, use of autoantibody testing should be guided by clinical symptoms. Autoimmune cytopenias are the most reported autoimmune condition in patients with IEI,<sup>453, 458</sup> but laboratory confirmation may be challenging as there is low sensitivity in anti-platelet and anti-neutrophil antibody testing and variability in laboratory testing methods.<sup>458-460</sup> Given the low positive and negative predictive values of autoantibody panel testing in patients with IEI, these tests should be reserved for confirmation in the setting of signs or symptoms suggestive of autoimmune or rheumatologic disease.<sup>458-460</sup>

Patients who are receiving antibody replacement therapy may have false-positive testing to some types of autoantibodies that are present in the donor population plasma pool.<sup>461-464</sup>

**RECOMMENDATION 7.5: We recommend the evaluation of major organ system functions and screening for cancer and mental health disorders in IEI patients.**

Strength of recommendation- **Strong**

Certainty of evidence- **High**

2451 It is critical to periodically assess for major organ system involvement in patients with  
2452 IEI. Infectious complications are commonly brought to clinical attention, but non-  
2453 infectious complications are associated with higher mortality<sup>8, 465</sup> and may be missed if  
2454 not screened at during visits. Early identification of non-infectious complications is  
2455 possible through diverse laboratory tests, imaging, and procedures. However, the  
2456 precise frequency and extent of surveillance of such interventions may vary with the  
2457 clinical complexity of each patient.<sup>465</sup>

2458 Clinical Exam: A thorough (at least yearly) clinical exam by a physician with expertise in  
2459 IEI should be integral to routine monitoring in patients with IEI.<sup>435, 466</sup> A skilled clinical  
2460 examination may prompt effective decision making leading to targeted laboratory  
2461 assessments.<sup>467</sup>

2462 Pulmonary: Clinical pulmonary assessment, inclusive of complete lung function testing  
2463 with diffusion capacity (DLCO) should be performed at baseline and at least on a yearly  
2464 basis in patients with IEI at risk for parenchymal lung disease or with a history of  
2465 recurrent lower respiratory tract infections.<sup>145, 466, 468-472</sup> This evaluation includes CT of  
2466 the chest for early detection of lung disease progression.<sup>145, 468, 471-474</sup> Repeated imaging  
2467 with low dose CT or MRI to decrease the cumulative radiation risk is recommended in  
2468 IEI with increased radiosensitivity.<sup>475, 476</sup> Pulse oximetry at rest and with exercise may  
2469 be helpful in patients with chronic lung disease to determine the need for oxygen  
2470 therapy.<sup>477</sup> The six-minute walk test is a simple cardiopulmonary functional testing  
2471 modality to assess aerobic capacity and endurance.<sup>478</sup>

2472 Gastrointestinal: Annual clinical exam should include assessment for hepato-  
2473 splenomegaly and presence of ascites. Serum liver enzymes should be assessed yearly  
2474 and undertaken more frequently if there is a high risk for autoimmune complications or  
2475 use of medications associated with hepatic toxicities.<sup>468</sup> In patients with IEI and  
2476 symptoms suggestive of gastrointestinal reflux, screening for *H. pylori* infection is  
2477 recommended.<sup>479-481</sup> Noninvasive screening for gastrointestinal infection  
2478 (gastrointestinal pathogen PCR panel) and inflammation (fecal calprotectin) should be  
2479 performed in patients with chronic lower gastrointestinal symptoms or weight loss.<sup>481, 482</sup>  
2480 For patients with a history suggestive of protein losing enteropathy (PLE), we  
2481 recommend stool alpha 1 antitrypsin (A1AT) testing.<sup>483</sup> Random A1AT fecal  
2482 assessments have proven to be as reliable as 24-hour A1AT assessments. Endoscopy  
2483 is recommended based on clinical presentation. Liver imaging with elastography  
2484 provides an assessment of liver stiffness (cirrhosis).

2485 Cardiac-Circulatory: Clinical cardiac and lymphatic examination should be performed at  
2486 least annually, assessing for pallor, petechiae, pedal edema, lymphadenopathy and  
2487 splenomegaly.<sup>468, 472, 480</sup>

2488 Nephrologic: Fluid retention and facial edema prompt evaluation of renal function.  
2489 Standard kidney function tests (i.e., serum creatinine as a surrogate marker) are

adequate and undertaken at least once a year if there is a high risk for autoimmune complications or medications associated with nephrotoxicity are used.<sup>468</sup> Serum cystatin C has a high sensitivity for identifying early kidney dysfunction. Known associations of kidney disease and IEI include IgA nephropathy in WAS<sup>484</sup> and aHUS seen in complement deficiencies.<sup>381</sup>

Dermatologic: Skin examinations should be performed at least annually, to screen for skin conditions associated with IEI including malignancies, skin infections, and vaccine-strain rubella granulomas. Skin biopsies and microbiological investigations are recommended for diagnosis accuracy.<sup>485-487</sup>

Endocrine and Bone Health: We recommend monitoring for signs/symptoms of immune endocrinopathies for patients with IEI, in particular immune regulatory disorders.<sup>488</sup> Targeted laboratory testing should be ordered directed by history and clinical examination.

Osteoporosis is often an overlooked complication in chronic care of IEI.<sup>489</sup> Bone density studies (DEXA scan) may be useful if there are concerns about chronic inflammation, height loss or evidence of malabsorption. Patients with abnormalities in IL-6 and IL-11 signaling, including STAT3-HIES, are at increased risk for reduced bone mineral density (BMD) and minimal trauma fractures.<sup>490</sup> We recommend screening for osteoporosis via bone densitometry starting at age 8 years old for those with a history of fractures.

Malignancy: Malignancy may be the initial manifestation or may develop after initial disease presentation of an IEI.<sup>491-493</sup> Patients with IEI have an increased risk for malignancy, with a reported prevalence between 4-25% depending on the underlying disorder.<sup>492, 494</sup> Hematologic malignancies are more common than solid tumors and Non-Hodgkin and Hodgkin lymphomas occur most frequently.<sup>493</sup> Therefore, close monitoring includes at least yearly physical exams. Significant unintended changes in body weight and systemic symptoms such as fevers should warrant a more in-depth evaluation for potential malignancy.<sup>468, 495</sup> Targeted biopsy and pathology examination may be indicated in cases of persistent or increasing lymphadenopathy or splenomegaly, to differentiate lymphoma from non-malignant lymphoproliferation. Tc-labeled splenic scan and PET scan may be useful in patients with concerns of asplenia or lymphoproliferation.<sup>337</sup> For IEI with increased radiosensitivity, imaging modalities that do not use radiation are preferred.<sup>476, 496</sup>

The clinician may encourage patients with IEI to adhere to United States Preventive Services Task Force (USPSTF) guidelines for cancer screenings (**Table 7.3**). All patients with IEI should be counseled to reduce their risk of cancer by choosing a healthy lifestyle including avoidance of known carcinogens, implementing regular exercise and a healthy diet, education on their risk of malignancy, cancer signs and symptoms, and self-examination, reducing both UVB and UVA exposure (i.e. use of sunscreen) and following recommended screening for skin cancer.<sup>497</sup>

The development of non-melanoma skin cancer occurs in two thirds of patients with epidermodysplasia verruciformis (EV).<sup>333</sup> Patients with deficient immunity to HPV are at increased risk for HPV-driven epithelial cancers.<sup>498</sup> We recommend that patients with IEI disorders at risk for HPV infection (e.g., EV) and IEI with cellular deficiencies be vaccinated against HPV<sup>499</sup> (**See Sections 10 and 11**). Patients should be educated on safe sex practices and females should undergo regular cervical cancer screening.

Myeloid disease, including myelodysplastic syndrome (MDS) and acute myeloid leukemia, are a common complication of many IEI with defects in hematopoiesis (e.g. *ELANE*, *SBDS*, *GATA2*). Current guidelines recommend regular surveillance of peripheral blood counts and annual bone marrow evaluation to include morphology, cytogenetics, and molecular investigation of clonal hematopoiesis.<sup>500</sup>

IEI associated with both non-malignant lymphoproliferation and increased risk of lymphoma (e.g., ALPS) may be difficult to manage in terms of cancer surveillance as imaging modalities will not differentiate between benign and malignant proliferation.<sup>501</sup> Concerns for malignancy in a lymph node should be confirmed with targeted biopsy and pathology examination.

**Table 7.3 – Examples of IEIs associated with increased cancer risk:**

IEI	Type of cancer and risk	Reference
DNA repair defects	Ataxia-telangiectasia: Leukemia (70-500-fold) and lymphoma (200-750-fold) Bloom syndrome: Intestinal cancer, leukemia, and lymphoma (150-300-fold)	502 503
Common variable immunodeficiency	Mucosa-associated lymphoid tissue (MALT) lymphoma Non-Hodgkin lymphoma (30-400-fold) Gastric cancer (10-fold)	504
Defects in <i>GATA2</i> , <i>CXCR4</i> , <i>STK4</i>	HPV-, EBV-associated cancers Chronic myeloid leukemia Acute myeloid leukemia Myelodysplastic syndrome Melanoma ( <i>GATA2</i> )	505 502 506
Epidermodysplasia verruciformis	Non-melanoma skin cancers	333
Wiskott Aldrich Syndrome	Lymphoma	502

Combined immune deficiencies: IL10R deficiency; AD-HIES	B cell lymphoma	502
Familial HLH ( <i>PRF1</i> )	Lymphoma	502
NK cell deficiency	EBV and hematologic malignancies	330
X-Linked Hyper IgM syndrome	Pancreatic and liver cancers	502

2547

2548 Neurologic and psychologic: Developmental milestones and behavioral concerns should

2549 be reviewed at each visit to monitor for developmental delay and behavioral disorders,

2550 which may occur in patients with IELs, especially SCID,<sup>507, 508</sup> as a consequence of the

2551 genetic defect, HSCT or secondary to an infection.

2552 Patients with chronic diseases are at higher risk for depression and other mental health

2553 concerns.<sup>509</sup> Studies of patients with IEL have shown up to 40% rates of psychiatric

2554 symptoms, particularly anxiety and depression,<sup>510-513</sup> as well as formal psychiatric

2555 diagnoses (odds ratio 1.91; 95% CI 1.66-2.01) and suicidal behavior (odds ratio 1.84

2556 95% CI 1.81-2.01),<sup>514, 515</sup> when compared to the general population. Patients with IEL

2557 also have high rates of fatigue,<sup>516-518</sup> which may be a somatic symptom of depression.

2558 Simple screening mental health questionnaires exist for adult and adolescent

2559 patients<sup>519, 520</sup> and may be incorporated into IEL patient visits.

## PART II; MANAGEMENT

### Section 8. Immunoglobulin replacement

#### **RECOMMENDATION 8.1: We recommend immunoglobulin replacement therapy (IgRT) for IEI with IgG antibody deficiency.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Immunoglobulin replacement therapy (IgRT) provides passive immunity in the form of polyclonal IgG to patients with IEI whose humoral immune response is absent or impaired, and who are at increased risk of serious bacterial infections. Early diagnosis and therapy are the keys to survival and improved quality of life for these patients.

Delays in initiating IgRT can result in permanent organ damage or death from overwhelming infection. IgRT is indicated for the treatment of patients with hypogammaglobulinemia and impaired humoral immunity and have been shown to prevent serious bacterial infections in these patients, inclusive of bacterial pneumonia, sepsis, bacterial meningitis, visceral abscesses, and osteomyelitis/septic arthritis.<sup>3, 522, 523</sup>

Adverse events associated with IgRT include fever, chills, malaise, fatigue, anxiety, rash, flushing, nausea, vomiting, headache, myalgia, back pain, arthralgia, tingling of extremities, hypo- or hypertension, tachycardia, fluid overload, and infusion site pain/swelling/erythema (for SCIG). These are generally mild, and rate or dose related, occurring in 5-15% of IVIG infusions, and more frequent in patients with active inflammation.<sup>522, 524, 525</sup> Severe adverse events are infrequent, usually occurring at the end of or post-infusion, and can include renal impairment, thrombosis, aseptic meningitis, hemolytic anemia, arrhythmia, and acute transfusion related lung injury (TRALI). Strategies that mitigate adverse events include slowing the rate of infusion (for intravenous administration) and administering premedication (**see below**). Slowing or stopping the IVIG infusion for 15-30 minutes will reverse many reactions.<sup>522</sup> Infusions can often be restarted at the last tolerated rate and then increased again. Another option frequently employed is switching to subcutaneous immunoglobulin (SCIG) IgRT, which is associated with fewer systemic adverse events.<sup>522, 526, 527</sup>

Premedication before IgG product infusions. If a patient experiences an infusion related adverse event with IVIG, pretreatment with ibuprofen or acetaminophen, and diphenhydramine or a nonsedating antihistamine (anti-H1) and/or hydrocortisone one hour before the infusion may prevent adverse reactions. Oral (or IV) hydration prior to the infusion is often used to prevent hypotension. A survey by the Immune Deficiency Foundation found that 34% of reactions occurred during the first infusion of an IVIG

product. After three treatments with the same product, additional infusion reactions become less likely.<sup>522</sup> Certain high-risk conditions such as renal failure, congestive heart disease, and diabetes mellitus need to be considered when evaluating the premedication with fluids because of the risk for fluid overload; or corticosteroids prior to each infusion because of the risk for hyperglycemia and hypertension.

Caution with central venous access devices. Benefits of ease of venous access provided using indwelling venous catheters for IVIG administration should be weighed against the thrombotic and infectious risks inherent in these devices which may be further amplified in patients with IEI and their use for the sole purpose of providing IVIG is not recommended. For patients with difficult venous access, consideration of administration of IgRT via the subcutaneous route is advised.<sup>2, 3, 522</sup> Significant adverse complications of IVIG administration include thromboembolic events, such as myocardial infarction, stroke, deep vein thrombosis, and pulmonary embolism. These adverse events are rare but have been reported in patients with IEI. Risk factors for these reactions include preexisting cardiovascular disease, diabetes mellitus, dehydration, age >65 years, sepsis, paraproteinemia, increased blood viscosity, hypercholesterolemia, and hypertension.<sup>522, 528</sup>

IgG products may not be equally tolerated. The AAAAI developed the Eight Guiding Principles for Effective Use of IVIG for Patients with Primary Immunodeficiency.<sup>522</sup> One of the Guiding Principles regarding product choice discusses that IVIG is not a generic drug and IVIG products are not interchangeable. To ensure patient safety, a change of IVIG product should occur only with the active participation of the prescribing physician. IVIG products have distinct characteristics including sodium content, osmolality, stabilizers and pH that should be considered in patients at risk for adverse effects. Long-term tolerance of one IVIG product does not necessarily equate to tolerance to another product. When switching IVIG products, adverse reactions during IgG infusion were reported in approximately 15-18% of patients.<sup>529</sup> A retrospective review analyzed 802 switches between immunoglobulin products between 2017-2018 due to supply issues,<sup>530</sup> twelve reactions were reported, none of which required admission to the hospital; one was treated with oral corticosteroids, and others required no treatment or treatment with oral antihistamines alone. These results contradicted the established guidelines regarding adverse reactions linked to product changes in the context of IEI with antibody deficiency, suggesting that there may be flexibility regarding immunoglobulin product switches for most patients; although safety of this practice is not predictable.

Pooled plasma for IgRT products is obtained from thousands of donors, inclusive of all ABO blood groups, therefore, plasma for IgRT products can contain various antibodies to blood cell antigens, including anti-A and anti-B IgG, which can lead to hemolysis. Although this is a rare occurrence, monitoring of blood cell counts is recommended for

this reason.<sup>531</sup> A higher incidence of IVIG-related hemolysis was consistently reported in patients with blood groups A and AB, occurred more frequently in patients treated with high dose IVIG for conditions such as Kawasaki disease, and the incidence was lower in studies using IVIG products whose manufacturing processes included steps to reduce isoagglutinin levels.<sup>532</sup>

The prescribing information for every IVIG product includes a warning about renal dysfunction, acute renal failure, osmotic nephrosis, and death. These renal complications were reported more commonly in patients receiving IVIG products containing sucrose.<sup>533</sup> Currently, in the US there are no IVIG products containing sucrose on the market. Incidences of renal impairment with sucrose-free IVIGs are similar between products and much lower than those seen with sucrose-stabilized IVIGs.<sup>533, 534</sup> In a case control study from 1996 to 2009, predictors of renal failure associated with IVIG included use of angiotensin-converting enzyme inhibitors, angiotensin receptor antagonists, use of diuretics, and age > 70 yrs, male gender, chronic kidney disease, hypertension, and diabetes mellitus.<sup>535</sup> Monitoring BUN and creatinine over time alert the clinician regarding adverse events related to kidney function during therapy.

Between 1983 and 1987 clusters of non-A, non-B hepatitis (i.e., hepatitis C) were reported after IVIG treatment, and in February 1994, one manufacturer instituted a worldwide recall of its brand of IVIG, because of reports of ten cases of possible transmission of hepatitis C. At that time, the production process for several IVIG products did not include steps for viral inactivation.<sup>536</sup> This led to the recommendation by the FDA to add solvent/detergent (S/D) to the manufacturing process to inactivate lipid envelope viruses. In the late 1990's Mad Cow Disease (a variant of Creutzfeldt-Jakob disease) emerged in Europe. To address this pathogen safety, all immunoglobulin products utilize nanofiltration to remove possible prion contamination in donor plasma.<sup>537</sup> There have been no further reports of transmission of hepatitis or other infectious agents from IVIG products since the addition of additional pathogen inactivation/exclusion steps. Nonetheless, monitoring of liver function tests is often routine in the management of patients on IgRT.

**RECOMMENDATION 8.2: We recommend that initial dosing of immunoglobulin for replacement therapy be at 400 mg/kg-600 mg/kg per month, followed by dose adjustment if necessary.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

IgRT dosing is recommended to start at 400 mg/kg-600 mg/kg every 3-4 weeks, when given intravenously, followed by dose adjustment to obtain clinical efficacy, and for changes in body weight >5% of baseline. When the subcutaneous route is used, this

dose is given in divided weekly or biweekly infusions. This dosing range achieves adequate serum IgG trough levels resulting in prevention of serious bacterial infections. However, serum IgG levels required for improved infection control vary among patients.<sup>538, 539</sup> In one study using an IgRT dosing range from 200 to 1200 mg/kg/month, patients with XLA required trough serum levels from 800-1300 mg/uL to stay infection free, while a cohort of CVID patients required a range of trough levels from 500-1700 mg/uL to prevent breakthrough bacterial infections (**see RECOMMENDATION 8.4**).<sup>538</sup>

**RECOMMENDATION 8.3: We recommend monitoring of serum IgG levels, complete blood counts with differential, and serum chemistry levels for patients on immunoglobulin replacement therapy.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

Regular monitoring of trough or steady state serum IgG levels allows clinicians to assess patient compliance with therapy, monitor potential adverse effects, and define the IgG level at which their risk of infection is best controlled.<sup>538-541</sup> Serum IgG levels during IgRT provide supporting evidence of the ongoing therapeutic effect and need for IgRT to maintain these levels. A declining trend of serum IgG levels suggests the need of increasing IgRT dosing.

When patients on IgRT consistently receive infusions at recommended intervals (usually every 3-4 weeks for IVIG and every 1-2 weeks for SCIG) the serum IgG level is expected to vary depending on the pharmacokinetics and dose of the product. For IV administration, the IgG level is highest hours after infusion and levels drop steadily over 3-4 weeks. With SC administration, maximum IgG levels occur around 3-5 days post-infusion and decrease slowly. After 4-6 months of weekly or biweekly SC infusions serum IgG levels are consistent with steady state kinetics.<sup>542-544</sup> Due to differences in the kinetics of absorption as well as the distribution in extravascular spaces, dose adjustments are recommended by some U.S. manufacturers in initiating therapy. The recommendations vary from increasing dosing of SCIG from 1.35 to 1.53 times the calculated IVIG dose. These recommendations are intended to provide IgG levels that approximate the same bioavailability for SCIG and IVIG.<sup>543, 545</sup>

We recommend checking the serum IgG levels every 6 months to every year, in clinically stable patients receiving IgRT. However, a more frequent (i.e., monthly) monitoring of IgG levels is appropriate in patients who continue to have breakthrough bacterial infections, have underlying comorbidities (such as protein losing conditions), take immunosuppressive therapies, have significant weight changes, or who may not be adherent with therapy.

**RECOMMENDATION 8.4: We recommend maintaining serum IgG levels at >800mg/dl to improve outcomes.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

The goal of IgRT therapy is to improve clinical outcomes and prevent serious bacterial infections. In addition, individualization of dose according to patient response to therapy is important, given the variability between patients. This is illustrated by the concept of a “biologic trough” referring to the IgG trough level above which patients are infection free.<sup>546</sup> The biologic trough IgG level varies between individuals depending on the underlying disorder and comorbidities.<sup>538</sup> A meta-analysis of IVIG studies concluded that serum trough IgG levels 800 mg/dl – 1000 mg/dl are associated with significantly less occurrence of pneumonia.<sup>547</sup> Incidence of pneumonia declined by 27% with each 100 mg/dl increment in trough IgG, and the incidence of pneumonia with a maintenance trough IgG level of 500 mg/dl was 5-fold higher than with trough IgG levels of 1000 mg/dl (0.113 cases per patient year vs 0.023 cases per patient year respectively). No benefit was seen at trough IgG levels higher than 1000 mg/dL. An analysis of available SCIG studies reported a similar inverse correlation between the annual rate of infection and the serum trough IgG concentrations.<sup>548</sup>

**RECOMMENDATION 8.5: We recommend that immunoglobulin replacement therapy is indicated as a continuous therapy for IEI**

Strength of recommendation: **Strong**

Certainty of evidence: **Low**

Continuous and uninterrupted immunoglobulin replacement therapy is indicated for IEI with defects in humoral immunity. Immunoglobulin therapy *with polyvalent human IgG* is an essential, life-saving therapy for these patients. Only in selected cases, (such as specific antibody deficiency in children or transient hypogammaglobulinemia of infancy) it may be clinically appropriate to stop immunoglobulin therapy temporarily to determine if the antibody deficiency has resolved over time. This strategy should not be repeated if the trial indicates a persistent deficit of IgG production.<sup>522, 549</sup>

**RECOMMENDATION 8.6: We recommend that low or absent IgA, in the setting of low IgG levels, is not a contraindication for immunoglobulin replacement therapy.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

Intravenous administration of IgRT has been associated with a risk for anaphylaxis in IgA-deficient patients who have anti-IgA IgE antibodies and a risk of reactions due to

complement activation if IgG anti-IgA antibodies are present. However; most patients who have low serum IgA, with or without IgG anti-IgA antibodies, receive IVIG without difficulty, regardless of the IgA content.<sup>522, 550-552</sup>

A retrospective and prospective observational study evaluated the possible association of IgG and/or IgE anti-IgA with adverse reactions in a subgroup of IgA-deficient patients receiving immunoglobulin replacement and was unable to conclude any increased risk for adverse reactions associated with IgA deficiency. The investigators suggested that in an individual patient, the presence of IgG anti-IgA might be a biomarker of increased risk for non-IgE-mediated anaphylactoid reactions to immunoglobulin infusion containing IgA, but studies are needed to determine whether class- or subclass-specific IgG anti-IgA antibodies have any clinical relevance.<sup>552</sup>

Regardless of IgA level, in any patient who is having significant systemic symptoms with IVIG, switching to SCIG or use of IgA-depleted IgRT product should be considered.<sup>522, 550-552</sup>

**RECOMMENDATION 8.7: We suggest that the route of immunoglobulin administration be determined based on patient tolerance and preference.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Moderate**

Many studies support equivalence of effectiveness and safety between SCIG and IVIG therapy for the management of antibody deficiencies.<sup>522</sup> The decision to infuse immunoglobulins in a hospital, hospital outpatient, community office, or home-based setting and the route of immunoglobulin administration whether IV, SC must be based upon the clinical characteristics of the patient.<sup>522</sup>

There is a reduced incidence of systemic adverse events with SCIG, increased flexibility in scheduling and shorter infusion times as compared with IVIG, but requires independence and good adherence on the part of the patient or parent, the confidence of the physician and the nurse, and more frequent dosing as well as increased number of needle sticks.<sup>522, 553</sup> A form of SCIG is “facilitated SCIG”, using the addition of hyaluronidase to the IgRT product to increase the amount of volume of immunoglobulins (up to four times) infused at once into the subcutaneous tissue, allowing to reduce the frequency of infusions, SCIG therapy may be preferred in select patient populations, including children, pregnant women, and patients with difficult intravenous access.<sup>553</sup> Studies have shown enhanced quality of life in patients receiving SCIG compared with IVIG therapy, mostly due to the freedom to administer SCIG at home and at the patient’s convenience.<sup>522</sup> This benefit results in greater patient satisfaction and fewer missed days of work or school for infusion-clinic appointments.<sup>522, 554, 555</sup> Initial infusions are done under supervision by a health care professional,

providing training for subsequent self-infusions at home.<sup>555</sup> Patients with reduced manual dexterity, who cannot self-administer, or who prefer less frequent treatments may have most success with IVIG administration by medical staff in a clinic, infusion center or at home. A useful and comprehensive algorithm based on individual clinical outcomes and patient-related factors relating to immunoglobulin therapy may assist in shared decision making.<sup>555</sup>

## **Section 9. Infection Prevention in IEI**

### **RECOMMENDATION 9.1: We recommend targeted antimicrobial prophylaxis for IEI patients with increased susceptibility to infections.**

Strength of recommendation: **Strong**

Quality of evidence: **High**

#### **Prophylaxis for Selected IEI:**

##### **CGD**

Trimethoprim-sulfamethoxazole (TMP/SMX) is an ideal antibiotic for prophylaxis in CGD as it covers the most common bacterial infections, namely *Staphylococcus aureus*, *Burkholderia cepacia*, *Serratia marscens*, and *Nocardia* species (**Table 9.1**).<sup>556</sup> Retrospective studies demonstrated a decrease of bacterial infections by approximately 50% with the use of TMP/SMX prophylaxis.<sup>556-558</sup> Drug desensitization is suggested when there is concern for hypersensitivity to TMP/SMX. Alternatives, which have gaps in the CGD pathogen coverage, are second or third generation cephalosporins or trimethoprim alone.

Antifungal prophylaxis with itraconazole decreased the frequency of fungal infections in a placebo-controlled crossover study: seven patients were diagnosed with invasive fungal infection while on placebo compared to one invasive fungal infection on itraconazole.<sup>559</sup> Liquid itraconazole has better absorption than tablets but may pose adherence concerns. Itraconazole tablets should be taken with a meal, and ideally with an acidic food such as orange juice. It is important to note that itraconazole and other azoles have many drug interactions; itraconazole can inhibit the metabolism of corticosteroids (**Table 9.2**). Other antifungal triazoles, including posaconazole, voriconazole and isavuconazole have not been studied, but are likely effective for prophylaxis. Voriconazole can be associated with photosensitivity and increased risk of skin malignancies<sup>560</sup> as well as fluorosis.<sup>561</sup>

Prophylactic interferon gamma (IFN  $\gamma$ ) is frequently used in addition to antimicrobial prophylaxis in CGD. A randomized placebo-controlled study performed in the early

1990s showed that IFN  $\gamma$  reduced the rate of serious infections by two-thirds and decreased the frequency and length of hospitalization.<sup>562</sup> Importantly, this study was performed prior to standard use of prophylactic antifungals for CGD patients; therefore, the impact of IFN  $\gamma$  is not known when given with itraconazole and TMP/SMX. A meta-analysis of published literature identified 3 case-control studies reports the risk ratio for serious infection was 0.56 (95%CI 0.35-0.90) when using IFN- $\gamma$ .<sup>563</sup> Some patients experience flu-like side effects with IFN  $\gamma$  doses, which can be ameliorated with night-time dosing and antipyretics. IFN  $\gamma$  is typically not used during treatment of acute infections, due to side effects of fever and elevated inflammatory markers that may confuse the assessment of therapeutic response to antimicrobials.

#### SCID/athymia prior to immune reconstitution.

Infections prior to immune reconstitution with definitive therapy (HSCT, gene therapy, or cultured thymic tissue implantation) are associated with increased morbidity and mortality.<sup>59, 77</sup> TMP/SMX is recommended as first-line *Pneumocystis* prophylaxis, starting at one month of age due to case reports of drug-induced liver injury and hyperbilirubinemia in the neonatal period. (**Table 9.2**) Alternative agents include pentamidine (typically intravenous in infants and inhaled in adults), oral atovaquone, and dapsone (assuming normal G6PD levels). (**see Section 2**)

*Candida* infections are the most common fungal infections in SCID, typically causing mucocutaneous disease. Prophylaxis is recommended with fluconazole.<sup>77</sup> Nystatin topical suspension can be utilized in the neonatal period in lieu of fluconazole.

HSV prophylaxis is recommended only if the patient has risk factors for HSV infection, such as maternal active disease.<sup>77</sup> Acyclovir should not be given if the patient is currently receiving ganciclovir or valganciclovir. CMV prophylaxis is discussed under **Section 2.4**, and **Table 9.1**.

Prophylaxis with azithromycin or clarithromycin has been suggested for patients with athymia who received thymus implantation as three cases of disseminated NTM were reported in these infants.<sup>564</sup>

#### Antibody deficiencies.

Antibody deficiencies, such as CVID and XLA, are characterized by recurrent sinopulmonary infections, predominantly with encapsulated bacteria such as *S. pneumoniae* and *H. influenzae*, and less frequently with *S. aureus* or other organisms. The airway flora may change if bronchiectasis develops, with more Gram-negative bacteria including *Pseudomonas*. IgRT is the mainstay of therapy to replace the IgG deficit.<sup>547</sup> However, if patients continue to have breakthrough bacterial infections despite optimal dosing of IgRT, then antibiotic prophylaxis, such as azithromycin, amoxicillin, or TMP/SMX should be considered as an additional preventive therapy.<sup>565-567</sup> If chronic lung disease such as bronchiectasis is present, azithromycin is recommended as the

antibiotic prophylaxis of choice due to antimicrobial and anti-inflammatory properties.<sup>568</sup> In a randomized placebo-controlled study involving adult patients with primary antibody deficiencies and chronic lung disease on IgRT, azithromycin decreased the frequency of lung exacerbations, hospitalizations, and antibiotic courses.<sup>569</sup> Azithromycin can be dosed either 3 days/week at 250 mg as in the randomized study, at 500 mg 3 days/week as in cystic fibrosis, or daily at 250 mg.

Patients with XLA are at risk for disseminated infections with typically gastro-intestinal restricted bacteria including *Campylobacter* and *Helicobacter* species<sup>570</sup>; some of these organisms are azithromycin sensitive, and thus prophylaxis may decrease the disseminated infections. *Mycoplasma* infections can also cause disseminated infections, such as arthritis, and may be targeted with azithromycin prophylaxis.

Specific antibody deficiencies, transient hypogammaglobulinemia of infancy, and mild hypogammaglobulinemia may be associated with recurrent sinopulmonary infections. In these settings, a retrospective experience showed a trial of antibiotic prophylaxis is an alternative first line approach, with benefit in converting to IgRT there is not an improvement.<sup>566, 571, 572</sup>

#### Complement defects and asplenia.

Terminal complement defects and asplenia are associated with severe and disseminated infection with encapsulated bacteria including *S. pneumoniae*, *N. meningitidis*, and *H. influenzae*. Vaccination against these organisms are the mainstay for prevention of infection. (**See Section 11**). In addition, antibiotic prophylaxis, amoxicillin or penicillin, is recommended for children through at least 5 years of age, but can be considered lifelong, especially for those with a history of sepsis.<sup>573, 574</sup> For those with penicillin allergy, cephalosporins such as cephalexin, or azithromycin, are the alternatives. An evaluation for penicillin allergy may be preferred prior to considering the second-line drugs.<sup>573, 574</sup>

#### Hyper IgE syndrome due to STAT3/IL-6 signaling pathway defects and recurrent infections.

Hyper IgE syndromes caused by defects in STAT3 and IL-6 signaling are characterized by recurrent skin and lung infections as well as eczematoid dermatitis. Recurrent *S. aureus* pneumonia results in pneumatoceles and bronchiectasis.<sup>575, 576</sup> Prophylaxis against *S. aureus* is recommended, typically with TMP/SMX. In addition, if atopic dermatitis is present, use of antiseptics for bathing (e.g., dilute bleach baths or chlorhexidine) can decrease the colonization of skin by *S. aureus*, decreasing skin infections and improving eczema. Antifungal prophylaxis for HIES is discussed below.

#### Prophylaxis for Specific Pathogens and Settings:

2903 Anti-*Pneumocystis jirovecii* pneumonia (PJP) prophylaxis.

2904 Patients with T cell deficiencies and combined immune defects (CID) such as  
2905 CD40L/CD40 deficiency, DOCK8 deficiency, and Wiskott-Aldrich syndrome, are at risk  
2906 for PJP, and prophylaxis should be provided with TMP/SMX or alternatively,  
2907 pentamidine (IV or inhaled), atovaquone, or dapsone (in G6PD sufficient patients).<sup>577-579</sup>  
2908 In addition, PJP prophylaxis is recommended in IEI with immune dysregulation with  
2909 decreased cellular immunity due to immune suppression.

2910 Antiviral prophylaxis.

2911 Various IEI, including SCID/athymia, CID, and certain innate defects, have increased  
2912 risk for viral infections. Viral prophylaxis for SCID/athymia are discussed in **section 2.4**.  
2913 Antivirals are limited in oral formulations and anti-viral activity. Acyclovir or valacyclovir  
2914 are used for HSV and VZV prophylaxis for IEI at risk for recurrent or severe infections,  
2915 such as defects of the TLR3 pathway.<sup>331, 580</sup> After high risk VZV exposure, varicella  
2916 immune globulin can be considered for varicella-susceptible patients at risk for  
2917 disseminated disease. As an alternative, a dose of immune globulin (400 mg/kg) can be  
2918 considered within 10 days of exposure (if the patient is not on IgRT) or acyclovir or  
2919 valacyclovir prophylaxis for 7 days starting 7-10 days after exposure.<sup>581</sup>

2920 Patients with innate defects along the IFN $\alpha$  signaling pathway are at high risk for certain  
2921 infections such as influenza and SARS-CoV-2.<sup>582-584</sup> Inactivated vaccines for viral  
2922 respiratory tract infections (e.g., influenza, SARS-CoV-2) are recommended to patients  
2923 and household contacts. The use of live viral vaccines should be avoided by these  
2924 patients. Influenza antiviral prophylaxis is recommended after high-risk exposure to  
2925 Influenza, typically with oseltamivir (oral) or zanamivir (inhaled).<sup>585</sup>

2926 Seasonal RSV prophylaxis is recommended for patients with SCID or congenital  
2927 athymia prior to immune reconstitution, and for patients with other IEI up to 24 months  
2928 of age.<sup>77</sup>

2929 Nontuberculous mycobacteria (NTM) infection prophylaxis.

2930 Defects affecting the IL-12/IFN  $\gamma$  /STAT1 pathway, defects affecting NF- $\kappa$ B activation  
2931 (NEMO, I $\kappa$ B $\alpha$ ), and other MSMD defects are at high risk for disseminated NTM and  
2932 BCG infection.<sup>345, 586</sup> Neonates born to families with history of these defects should not  
2933 receive BCG vaccination until diagnostic studies confirm absence of IEI. Antibiotic  
2934 prophylaxis against NTM, such as azithromycin, should be provided after exclusion of  
2935 active mycobacterial infection, primarily by clinical assessment, AFB cultures, and/or  
2936 imaging.

2937 Antifungal prophylaxis.

2938 Certain IEI predispose to chronic mucocutaneous candidiasis (CMC), including STAT3  
2939 HIES, STAT1 GOF, APECED, CARD9 deficiency and defects of IL-17 and its  
2940 receptor.<sup>335, 587, 588</sup> For patients with frequent candidal infections, antifungal prophylaxis

with fluconazole is recommended. For patients with STAT1 GOF treated with JAK inhibitors, the CMC may improve, and azole prophylaxis may be stopped.<sup>589</sup> Certain IEI, namely STAT3 HIES and STAT1 GOF can be associated with severe disseminated coccidioidomycosis, therefore antifungal prophylaxis is recommended in endemic regions (i.e., southwestern United States and Northern Mexico).<sup>590</sup> In addition, STAT3 HIES is associated with pneumatocoeles that can be secondarily infected with *Aspergillus* or other molds; therefore, when pneumatocoeles are present, a mold-specific antifungal (e.g., itraconazole) should be used as prophylaxis. CARD9 deficiency is associated with disseminated *Candida* infections, including meningitis, and anti-fungal prophylaxis is suggested.<sup>591</sup>

#### Peri-operative *S. aureus* prophylaxis.

Surgery can be associated with impaired wound healing and post-operative infections in patients with IEI.<sup>592, 593</sup> For IEI susceptible to *S. aureus* infections, such as neutrophil defects (e.g., CGD, LAD) or STAT3 and IL-6 related HIES, we suggest measures to decrease bacterial burden pre-operatively, such as with nasal mupirocin and/or chlorhexidine or dilute bleach baths. Peri-operative antibiotics directed against *S. aureus* are also suggested in these cases.

#### Airway clearance peri-operatively

Patients with IEI complicated by bronchiectasis or other forms of chronic lung disease may have increased risk during surgeries due to decreased airway clearance associated with anesthesia and decreased activity. Communication between the surgeons and the IEI expert to optimize airway clearance peri-operatively is suggested. Methods to improve airway clearance post-operatively include increased activity to diminish time in bed, hypertonic saline nebulizations, airway clearance devices, and consideration of inhaled medications (e.g., tobramycin) for those with chronic *Pseudomonas* colonization.

#### Dental procedures in IEI patients.

Dental work is inherently associated with disturbance of the oral flora, typically with streptococcal species and anaerobes. Individuals with neutropenia or functional neutrophil defects are at greater risk for infections from these organisms. Other IEI such as STAT3/IL-6 HIES are associated with dental abscesses. With extensive dental work, such as extractions, root canals, deep scaling and implant placement, we suggest antibiotic prophylaxis such as with amoxicillin/clavulanate or clindamycin. Patients with other forms of immunodeficiency, particularly isolated antibody deficiencies, do not typically require antibiotic prophylaxis for invasive dental work.<sup>594</sup>

#### Caution with use of multiple antimicrobials.

2977 Patients with IEI often receive multiple antimicrobials and are at increased risk of  
 2978 adverse drug reactions. Involving a pharmacist may be helpful for close review of  
 2979 antimicrobials, facilitate drug monitoring, dosing and therapeutic optimization.<sup>595</sup>

2980

2981 **Table: 9.1 Antibiotic Prophylaxis for Selected IEI**

IEI	Indication for prophylaxis	Drug regimen	Organisms covered	Strength of recommendation	Certainty of evidence	References
CGD	Severe bacterial infection: pneumonia, skin abscess	TMP/SMX (5 mg/kg max dose 160 mg TMP component twice daily). Alternatives: cephalosporins, doxycycline.	<i>S. aureus</i> , Burkholderia spp, Nocardia spp, Serratia spp	Strong	High	557
	Invasive Aspergillus (lung, bone)	Itraconazole 5 mg/kg daily, max daily dose 100 mg (< 50kg), 200 mg (>50kg)	<i>Aspergillus</i> spp	Strong	Moderate	559
	All infections	IFN $\gamma$ 50 ug/m <sup>2</sup> (min 1.5 ug) SC injection 3 days/week		Strong	Moderate	562 563
SCID, congenital athymia	<i>Pneumocystis</i> pneumonia	TMP/SMX (5 mg/kg max dose 160 mg TMP component twice daily). Alternatives: pentamidine, atovaquone, dapsone	<i>Pneumocystis jirovecii</i>	Strong	High	59 77
	Candidiasis, fungal infection	Fluconazole 5 mg/kg	<i>Candida</i> spp	Strong	High	59 77
	Prevention/ Treatment of CMV viremia, pneumonia, hepatitis, CNS infection	Acyclovir 5 mg/kg Ganciclovir Valganciclovir 16 mg/kg/day Treat until infant is CMV PCR negative weekly x 4	CMV, HSV infection.	Strong	Low	59 77
Antibody Deficiencies	Respiratory infections	Azithromycin (5 mg/kg/day. max of 250 mg daily or	<i>S. aureus</i> , <i>S. pneumoniae</i> , <i>H. influenzae</i> , <i>M. catarrhalis</i>	Conditional	Low	567 569

		500 mg 3 days/week) Alternatives: Amoxicillin TMP/SMX				
Terminal Complement defects or asplenia	Sepsis, meningitis with encapsulated bacteria	Amoxicillin or Penicillin daily or through 5 years of age May continue lifelong	<i>S. pneumoniae</i> , <i>Haemophilus influenzae</i> <i>N meningitidis</i>	Strong	moderate	573 574
STAT3/IL-6 related HIES	Bacterial Infection	TMP/SMX dose: 5-6 mg/kg/day (divided BID)	<i>S. aureus</i>	Conditional	Low	575 576
	Chronic mucocutaneous Infection	Fluconazole (if not on itraconazole or other triazoles) 5 mg/kg	<i>Candida</i> species CMC Coccidioides if endemic region	Conditional	Low	590
	Prophylaxis against Aspergilloma	Itraconazole 5 mg/kg daily, (max 100 mg/day < 50kg, 200 mg day >50kg) Treat if pneumatocele present	<i>Aspergillus</i> spp.	Conditional	Low	575
Chronic Mucocutaneous Candidiasis (STAT1 GOF, APECED, CARD9, IL17 and IL17R defects)	Disseminated candidiasis or Coccidioidomycosis	Fluconazole 5 mg/kg	<i>Candida</i> spp; Coccidioides	Conditional	Low	589
MSMD	Mycobacterial infections	Azithromycin (5 mg/kg/day. max of 250 mg daily or 500 mg 3 days/week)	Environmental mycobacteria	Conditional	Moderate	586 345

CID with severe T cell defects	<i>Pneumocystis pneumonia</i>	TMP/SMX (5 mg/kg max dose 160 mg TMP component twice daily). Alternatives: pentamidine, atovaquone, dapsone	<i>Pneumocystis jirovecii</i>	Conditional	Low	578 579
	Chronic viral infection	Acyclovir 5 mg/kg Ganciclovir  Valganciclovir 16 mg/kg/day	HSV/VZV	Conditional	Low	580
	GI infection	Azithromycin  (5 mg/kg/day. max of 250 mg daily or 500 mg 3 days/week)	<i>Cryptosporidium</i>	Conditional	Very Low	None

TMP/SMX Trimethoprim sulfamethoxazole; CGD Chronic Granulomatous Disease; Tx treatment; PJP Pneumocystis jirovecii pneumonia; CMC Chronic Mucocutaneous Candidiasis; CMV cytomegalovirus; PCR polymerase chain reaction; WAS Wiskott Aldrich Syndrome; PAD Primary Antibody Deficiency; HIES Hyper IgE Syndrome; HSV Herpes Simplex Virus ; VZV Varicella Zoster Virus ; NTM Non Tuberculous Mycobacteria; DN Double Negative

**Table 9.2: Special considerations for antibiotic treatment in at risk individuals**

Special Antimicrobial Considerations	
Neonates	TMP/SMX can cause hyperbilirubinemia in neonates; prophylaxis may be delayed until approximately 4 weeks of age.
Pregnancy	Many antimicrobials used in IEI bear increased risks including but not limited to TMP/SMX, azoles, tetracyclines and fluoroquinolones, and require risk/benefit discussions
Photosensitivity	Voriconazole and doxycycline, and less frequently TMP/SMX can cause photosensitivity, and long-term voriconazole has been associated with skin cancers.
EKG abnormalities	Several antimicrobials used in IEI can be associated with prolonged QTc such as azithromycin, fluoroquinolones, certain azoles, and need monitoring for this arrhythmia.

**RECOMMENDATION 9.2: We recommend using only irradiated, cytomegalovirus (CMV)–negative, lymphocyte-depleted blood products for administration to patients with cellular or combined IEI.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

For patients with SCID, congenital athymia or CID, care should be taken not to avoid CMV infection by using CMV negative, lymphocyte depleted irradiated blood products. Patients with suspected or known SCID or athymia as well as their mothers should be evaluated for CMV status, breastfeeding withheld, and formula given, if feasible until maternal CMV status is known<sup>77</sup> (**see RECOMMENDATION 2.4**). Newborns should be screened with blood and urine CMV PCR and the mother's CMV serostatus should be evaluated. If the newborn is found to be infected with CMV or develops symptoms consistent with CMV infection while PCR is pending, ganciclovir (6 mg/Kg IV twice daily) or valganciclovir (16 mg/Kg IV twice daily) therapy should be started and subsequently continued until immune reconstitution. If the mother is found to be CMV seropositive, ganciclovir or valganciclovir should be started until weekly patient's urine and blood PCRs are negative for CMV for 4 weeks. CMV disease is seen much less commonly in other IEI, but asymptomatic viremia can be present in CID patients. In this setting, examination for signs of disease, such as hepatitis, pneumonitis, chorioretinitis, or enteritis, is prudent, and suppression of viremia prior to HSCT is recommended if HSCT is planned.

**RECOMMENDATION 9.3: We recommend educating patients regarding environmental exposures that may increase the risk of infections for patients with IEI.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

Large inhalational exposures of mold can cause overwhelming pulmonary fungal infection. In patients with CGD, this condition is referred to as "mulch pneumonitis" and causes diffuse infiltrates on chest imaging and potentially significant hypoxemia.<sup>596</sup> Treatment involves antifungal medications, the addition of antibiotics for a mixed pathogen infection, and systemic corticosteroids. In STAT3-HIES, pneumatocèles can become infected with *Aspergillus* (e.g., aspergillomas) or other molds that can lead to chronic infection and significant hemoptysis.<sup>597</sup> Large mold inhalations can lead to ABPA-type presentations. Examples of activities with high risk for mold exposure include hayrides, playing or working with mulch, and marijuana smoking.

Endemic fungi, such as *Histoplasma*, *Blastomyces*, *Coccidioides*, and *Cryptococcus* can cause disseminated infection in certain IEI. These infections are seen with STAT3-associated HIES, STAT1 GOF, and less frequently with IFN $\gamma$  R defects and CIDs.<sup>335, 598</sup> Patients should be counseled regarding high-risk exposures to mold. Those at high risk for disseminated *Coccidioides* should be placed on prophylaxis when visiting endemic regions (i.e., Southwestern United States and northern Mexico). High risk activities for histoplasmosis include exploring caves with bat exposures and construction work.

*Cryptococcus* can be acquired from soil, particularly when contaminated with bird droppings.

Fresh and salt water can be contaminated with parasites or bacteria that cause significant infection in patients with IEI. Patients with neutrophil defects, such as CGD, are susceptible to uncommon infections by water-based bacteria, such as *Chromobacterium violaceum*.<sup>599</sup> Therefore, patients with CGD are encouraged to swim only in chlorinated or saltwater swimming pools.

Some CIDs, including CD40 ligand deficiency, DOCK8 deficiency and IL-21R deficiency are susceptible to chronic *Cryptosporidium* infections that can lead to significant biliary disease and potentially portal hypertension.<sup>600-602</sup> Treatment requires immune reconstitution, typically with HSCT, which can be challenging if liver disease is present. Avoiding high risk exposures such as water parks or public water fountains and drinking safe (filtered or boiled) water are helpful, along with screening patients with diarrhea and/or signs of cholestatic disease.

Antibody deficiencies are associated with giardiasis and other bacterial intestinal infections such as *Campylobacter*.<sup>570, 603</sup> Ensuring access to safe water, avoiding drinking from streams, lakes, or creeks, and using good hand washing and cooking techniques can minimize these infections.

**RECOMMENDATION 9.4: We suggest prompt diagnostic testing in patients with IEI presenting with acute infection symptoms and treatment with antimicrobial regimens with duration longer than recommended for immunocompetent patients.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Low**

Patients with severe IEI may lack cardinal signs of inflammation and infection, such as fever or elevated white blood cell counts or inflammatory markers. Therefore, subtle changes in clinical status or inflammatory markers should lead to in depth evaluation and/or closer clinical follow-up than for patients without IEI. TLR pathway defects or STAT3/IL-6 associated HIES are examples of diseases that fall into this group. Patients should be educated on signs of infection and when to seek medical attention. Health care practitioners should have a low threshold to look for infections in patients with IEI and focus on the typical infections associated with the specific IEI. Cultures or other microbiologic techniques, such as viral pathogen multiplex PCR assays, should be performed whenever possible to identify the type of infection and to allow antibiotic sensitivities when feasible. As some infections can progress quickly in the setting of severe IEI (such as CID, quantitative neutrophil deficiency, or SCID), and thereby lead to significant morbidity and mortality, practitioners should have a low threshold to initiate

empiric antimicrobials, with cultures and definitive diagnosis obtained as quickly as feasible. Choice of antibiotic therapy should consider development of resistance to antibiotics and drug hypersensitivity. The antimicrobial drug spectrum is then narrowed based on culture results when it becomes available. Certain infections may require a longer course of therapy to reduce the risk of recurrence. Repeat imaging studies are suggested for severe pneumonias to guide length of therapy and to assess for development of bronchiectasis. Disseminated fungal and mycobacterial infections require longer courses of treatment with guidance from repeat imaging and laboratory markers. Some patients may continue to be treated with antimicrobials for secondary prophylaxis once therapy has concluded.

## **SECTION 10: Management of co-morbidities in IEI**

**RECOMMENDATION 10.1: We suggest that systemic comorbidities in patients with IEI be evaluated and managed with a multidisciplinary team with expertise in IEI-related comorbidities.**

Strength of recommendation: **Conditional.**

Certainty of evidence: **Moderate.**

Management of patients with IEI and systemic comorbidities should be provided by a multidisciplinary team knowledgeable of IEI. Depending on the specific manifestations, cross-specialty involvement can include dermatologists, endocrinologists, gastroenterologists, hematologists, infectious disease specialists, oncologists, pulmonologists, rheumatologists as well as a variety of other specialists.

Immunosuppressive, anti-inflammatory, and cytotoxic therapies are all used for the treatment of non-infectious manifestations and have been demonstrated to be effective. When choosing among therapeutic options for a particular complication in patients with IEI, the degree of immune suppression associated with treatment and underlying IEI-specific susceptibilities to infection are deciding factors (**Tables 10.1-10.4**).

Solid organ transplantation outcomes in IEI patients are mixed.<sup>604-606</sup> When possible, organ transplants should occur at centers with experience in treating patients with IEI.

### **Lung Disease (Table 10.1)**

Pulmonary complications of IEI are common, including infections and morbidity secondary to infection, (e.g., bronchiectasis). Antimicrobial prophylaxis for patients with bronchiectasis is discussed in **Section 9**. In addition, maintaining higher trough serum IgG levels in patients with bronchiectasis receiving IgRT may be helpful in preventing infection and slowing progression of disease (**see Section 8, RECOMMENDATION 8.2**).<sup>607</sup>

Granulomatous-lymphocytic interstitial lung disease (GLILD), a non-infectious complication, occurs at increased rates in patients with primary antibody deficiency (PAD). Although high dose glucocorticoids may be used to induce disease remission in GLILD, maintenance corticosteroids may result in relapse.<sup>608</sup> One effective approach for GLILD is the treatment with B cell depleting therapy (e.g., rituximab) or equivalent, in combination with maintenance anti-metabolite therapy (mycophenolate mofetil or azathioprine).<sup>609</sup> Duration of therapy is typically 12-18 months, with ongoing clinical, radiologic and laboratory monitoring. Relapse occurs in a subset of patients and the approach to therapy in these patients is similar to initial therapy.

Patients with STAT-3 HIES are prone to the development of pneumatocele following pneumonia.<sup>610</sup> These pneumatoceles may become colonized with pathogens including *Pseudomonas aeruginosa* or *Aspergillus*. Antimicrobial therapy is needed to avoid a cycle of re-infection (**see Section 9**). Surgical interventions may result in complications following thoracic surgery compared to other patients, the most commonly reported as bronchopleural fistula formation.<sup>593</sup>

**Table 10.1. Management of lung disease**

Manifestation	Associated IEI	Intervention/ management	Strength of recommendation	Certainty of Evidence	References
Granulomatous and lymphocytic interstitial lung disease (GLILD)	Antibody deficiency	Combination treatment: B cell depleting therapy (e.g., rituximab) + anti-metabolite therapy (mycophenolate mofetil or azathioprine)	Strong	Moderate	<sup>609</sup>
		High dose corticosteroids	Conditional	Moderate	<sup>608</sup>
Pneumatocele following lung infection	STAT3-HIES	Antimicrobial treatment Avoid surgical approach if possible	Strong	Moderate	<sup>610</sup>
Bronchiectasis	Antibody deficiencies	Avoid surgical approach if possible Periodic, at least annual, imaging of lungs with high resolution CT scan Maintain high trough serum IgG levels Airway secretion clearance measures	Strong	Moderate	<sup>610</sup> <sup>611</sup> <sup>608</sup> <sup>607</sup>

Abbreviations: GLILD – Granulomatous and lymphocytic interstitial lung disease; HIES – Hyper IgE syndrome

### **Gastrointestinal Disease (Table 10.2)**

As many as 30% of patients with IEI have gastrointestinal involvement including enteric and hepatic disease,<sup>612</sup> the treatment of which in general is similar to that of immune competent patients but with some special considerations outlined below.

Patients with antibody deficiencies may develop immune-mediated villous atrophy of the upper gastrointestinal tract that pathologically mimics gluten-sensitive enteropathy (celiac disease). It can be challenging to differentiate these two entities as serologies are unreliable in patients with antibody deficiencies. However, gluten avoidance is not helpful for patients who are negative for celiac-associated HLA markers.<sup>613, 614</sup> Instead, immunomodulatory therapy (e.g., enteral or systemic corticosteroids) is the mainstay of therapy.<sup>615</sup>

Chronic norovirus infection is associated with chronic diarrhea in patients with IEI and can lead to significant morbidity. There is no consensus regarding effective treatment. Suggested therapies include a trial of antimicrobials (e.g., nitazoxanide, ribavirin) and/or anti-inflammatory drugs (e.g., enteral steroids, enteral immunoglobulin, or biologics).<sup>181, 615-617</sup>

Inflammatory bowel disease associated with CGD (also referred to as CGD colitis) is treated with standard therapy including 5-aminosalicylates, corticosteroids, and ustekinumab.<sup>618</sup> Caution is advised with the use of TNF- $\alpha$  inhibitors in patients with CGD colitis due to the increased risk of infection observed in a small case series of patients.<sup>619-621</sup> CGD patients undergoing HSCT have demonstrated remission of CGD colitis.<sup>622</sup>

Liver abscesses are a common manifestation of CGD, the management of which includes both initial treatment with culture/biopsy directed antimicrobials in addition to systemic corticosteroids.<sup>623</sup> Surgical management with debridement or resection may be required.<sup>624</sup>

Nodular regenerative hyperplasia (NRH) is a difficult to treat cause of non-cirrhotic portal hypertension in patients with IEI. Aggressive medical and surgical management is required to prevent variceal bleeding and minimize complications.<sup>625-627</sup> End-stage disease is associated with significant morbidity and mortality, and liver transplantation may be followed by disease recurrence.<sup>605, 606</sup>

Autoimmune hepatitis occurs with increased frequency in patients with IEI.<sup>627</sup> Treatment with corticosteroids and non-specific immunomodulators such as azathioprine is often effective but where possible, precision therapy based on the underlying molecular defect is preferred. For example, abatacept has been shown to be effective in patients with CTLA4 haplo-insufficiency<sup>628</sup> and jakinibs have demonstrated efficacy in patients with STAT3 GOF.<sup>447</sup>

**Table 10.2. Management of gastrointestinal disease**

Manifestation	Associated IEI	Intervention/management	Strength of Recommendation	Certainty of Evidence	References

Villous atrophy of the upper gastrointestinal tract	Antibody deficiency	Immunomodulatory therapy, first-line (e.g., enteral or systemic steroids)	Strong	Moderate	614 615
		Do not avoid gluten unless patients have celiac-associated HLA markers	Strong	Moderate	613
Chronic norovirus infection	Antibody deficiency, CID	Antimicrobials (e.g., nitazoxanide, ribavirin) and/or diverse drugs (e.g., enteral steroids, enteral immunoglobulin)	Conditional	Very low	616 617
Inflammatory bowel disease	CGD	5-aminosalicylates, corticosteroids, ustekinumab	Conditional	Low	618
		Use TNF-alpha inhibitors with caution of risk of severe infection	Conditional	Moderate	619 620
		HSCT	Conditional	Moderate	622
Liver abscess	CGD	Initial treatment with culture and biopsy directed antimicrobials and systemic corticosteroids	Strong	High	623
		Surgical management with debridement or resection if medical management is inadequate	Strong	Moderate	624
Nodular regenerative hyperplasia of liver	Antibody deficiency, CGD	Medical and surgical management of non-cirrhotic portal hypertension to prevent variceal bleeding	Conditional	Low	625 626
		Liver transplantation is discouraged	Conditional	Low	605 606
Autoimmune Hepatitis	Antibody deficiency, PIRD	Corticosteroids, immunomodulators	Conditional	Low	627
		Precision therapy based on underlying molecular defect (e.g., abatacept, jakinibs)	Conditional	Low	628 447

Abbreviations: CGD – Chronic granulomatous disease; HLA – Human leukocyte antigen; HSCT – Hematopoietic stem cell transplant; PAD – Primary antibody deficiency; TNF – Tumor necrosis factor

### Dermatologic Disease (Table 10.3)

Cutaneous disease occurs in patients with IEI in several different forms. For a rash not responsive to empiric therapy, diagnostic skin biopsy with bacterial, fungal and mycobacterial cultures should be performed to guide treatment.

Granulomatous skin disease can occur in CID, CGD, and CVID. Granulomas can also be found in other organs, including lymph nodes, spleen, liver, lung, and the GI tract. Vaccine strain rubella has been isolated by PCR from skin granulomas in patients with SCID, CID (notably those with DNA repair defects), and has also been reported in

patients with hypogammaglobulinemia and defects of innate immunity.<sup>629</sup> Once attenuated rubella or other infection has been ruled out, first line therapy for skin granulomas is oral corticosteroids, followed by TNF-alpha inhibitors if refractory or unresponsive to corticosteroid therapy<sup>630</sup> with the caveat that TNF-alpha inhibitors should be used with caution in patients with CGD and other IEI with increased susceptibility to mycobacteria and fungal infections (**see Table 10.2**).

Atopic dermatitis is associated with many IEI and can be quite severe. It can also predispose patients to skin infections. Initial management should focus on improvement of skin barrier with emollient therapy and control of inflammation with topical corticosteroids.<sup>631</sup> For some patients, particularly those who have had recurrent bacterial skin infections, dilute bleach baths or swimming in chlorinated pools 2-3 times per week can be beneficial to decrease bacterial colonization on skin. However, this strategy has not been studied specifically in patients with IEI.<sup>632</sup> For severe or refractory disease, immunosuppression is a consideration, but increased risk for infection must be balanced carefully. Biologic therapy, specifically dupilumab, has been used successfully in patients with IEI, notably STAT3-related HIES, with improvement in skin disease and good safety.<sup>633</sup>

Cutaneous warts can be found in various SCID or CID due to inability to control human papilloma virus (HPV) infection. Anti-wart treatment in patients with IEI is challenging as some therapies rely on activation of the immune system to clear the warts and may require multiple strategies, including destructive therapies, topical immunostimulants, surgical excision, or ablation. Response to systemic therapies, including immunomodulation, is inconsistent. Mavorixafor has been approved for the treatment of WHIM (**see Section 13**).<sup>634</sup> Treatment is also imperative as lesions can progress to malignancy.<sup>429</sup> The role of HPV vaccination for prevention of disease in patients with immunodeficiency is not clear but should be considered (**see section 11**).

**Table 10.3. Management of dermatologic disease**

Manifestation	Associated IEI	Intervention/management	Strength of Recommendation	Certainty of Evidence	References
Rash not responsive to therapy	Various IEI	Use diagnostic skin biopsy with cultures as guidance for treatment	Strong	Very low	None
Granulomatous skin disease	CID, CVID, CGD	PCR/immunohistochemistry for attenuated vaccine strain rubella virus.	Strong	Moderate	<sup>629</sup>
		Topical corticosteroids for non-infectious rash	Strong	Moderate	<sup>630</sup>
		TNF-alpha inhibitors to treat progressive or refractory disease	Conditional	Very low	<sup>630</sup>

		imaging for extra-cutaneous granulomatous disease	Strong	Very low	<sup>629</sup>
Moderate-to-severe atopic dermatitis	HIES, WAS	Biologic/targeted molecular therapy for refractory disease	Strong	Moderate	<sup>631</sup>
		Adjunct measures to reduce colonization with <i>S. aureus</i>	Conditional	Moderate	<sup>632</sup>
Refractory warts	CID	Topical cytotoxic therapies (e.g., cryoablation, salicylic acid or 5-fluorouracil) and topical immunostimulants (e.g. imiquimod)	Conditional	Very low	<sup>429</sup>
		Mavoxixafor (for WHIM)	Strong	Moderate	<sup>634</sup>

Abbreviations: CGD – Chronic granulomatous disease; CID – Combined immunodeficiency disorder; CVID – Common variable immunodeficiency; HIES – Hyper IgE syndrome; TNF – Tumor necrosis factor; WAS – Wiskott-Aldrich syndrome

### Neurodevelopmental disorders

Speech, gross and fine motor delays are associated with many IEI, therefore, early intervention with physical, occupational and speech therapy is essential.<sup>635-637</sup>

### Rheumatologic and musculoskeletal disease (Table 10.4)

Bone health optimization should be considered with vitamin D replacement, if needed, and adequate calcium intake.<sup>490</sup> Treatment with bisphosphonates may not reduce fracture risk but is considered when there are recurrent fractures and osteoporosis. Patients with STAT3-HIES also frequently have retained primary teeth, and consultation with a dentist regarding the timing of extraction of retained incisors and molars is recommended.<sup>638</sup>

Inflammatory myopathy, connective tissue disease, and non-infectious arthritis occur in patients with antibody deficiencies and WAS. Physical activity has been shown to reduce symptoms such as fatigue and pain, and improve function and mental health.<sup>639</sup> Patients are more likely to adopt better health practices when recommended by their physician<sup>640</sup> and thus physical activity should be routinely recommended by physicians caring for patients with IEI.

Pharmacologic treatment of rheumatologic disease should be approached similarly to patients without immune issues, inclusive of NSAIDs, corticosteroids, and corticosteroid-sparing agents such as methotrexate, sulfasalazine, cyclosporine or biologics.<sup>449, 641-643</sup>

Relatives of patients with CVID and CGD who are carriers of pathogenic variants in disease-associated genes may develop SLE and SLE-like symptoms, secondary to the inflammatory response and the impaired clearance of apoptotic cells. Lupus-like autoimmunity has been reported with increased frequency in STAT3-HIES patients.<sup>315,</sup>

<sup>643-645</sup> These symptoms should be treated like SLE even in the absence of classic serologic findings since serology is not confirmatory in many patients and carriers.<sup>315, 644</sup>

Patients with WAS have a high incidence of small vessel vasculitis which affects the skin, gastrointestinal system, and kidney.<sup>449</sup> Aortic aneurysms were reported in five cases.<sup>646</sup> Treatment of vasculitis includes standard therapies such as corticosteroids, methotrexate, cyclophosphamide, azathioprine, rituximab as well as high dose IVIg.<sup>647, 648</sup>

**Table 10.4. Management of rheumatologic and musculoskeletal disease**

Manifestation	Associated IEI	Intervention/management	Strength of Recommendation	Certainty of Evidence	References
Reduced bone mineral density and minimal trauma fractures	STAT3-HIES	Vitamin D replacement, if needed, adequate calcium dietary intake and/or supplementation, bisphosphonate therapy	Conditional	Moderate	<sup>490</sup>
Retained primary teeth	STAT3-HIES	Consultation with dentist for extraction of retained incisors and molars	Strong	Moderate	<sup>638</sup>
SLE and SLE-like symptoms	Antibody deficiencies, CGD, CGD carriers,	Treat SLE	Conditional	Moderate	<sup>644</sup> <sup>315</sup>
Small-medium vessel vasculitis	Complement deficiency, WAS	NSAIDs, corticosteroids, methotrexate, cyclophosphamide, azathioprine, rituximab	Strong	Low	<sup>449</sup>
		High dose IVIG	Conditional	Low	<sup>647, 648</sup>
Inflammatory myopathy. Persistent non-infectious oligo- or poly-articular arthritis	Antibody deficiencies, WAS	NSAIDs, corticosteroids, and steroid-sparing agents such as methotrexate, sulfasalazine, cyclosporine, or biological agents	Strong	Moderate	<sup>641</sup> <sup>642</sup> <sup>643</sup>
		Physical therapy and exercise therapy	Strong	Moderate	<sup>639</sup>

Abbreviations: CGD – Chronic granulomatous disease; CNS – Central nervous system; HLH – Hemophagocytic lymphohistiocytosis; HSCT – Hematopoietic stem cell transplant; IVIG – Intravenous immunoglobulin; MAS – Macrophage activation syndrome; NSAID – non-steroidal anti-inflammatory drug; PAD – Primary antibody deficiency; TNF – Tumor necrosis factor; WAS – Wiskott-Aldrich syndrome

**RECOMMENDATION 10.2: We recommend prompt management of cytopenias and malignancies in patients with IEI**

Strength of recommendation: **Strong**.

Certainty of evidence: **Moderate**.

Patients with certain IEI have increased risk for hematologic and oncologic complications, including immune cytopenias, malignancy, cancer susceptibility, lymphoproliferation, and HLH/MAS (**see Tables 7.2 and 7.3**).<sup>649</sup> Malignancy development in individual IEIs can occur secondary to defects in DNA repair, cellular maturation, signaling or apoptosis; impaired cancer immunosurveillance; and recurrent infections with viruses such as EBV and HPV which can cause oncogenic transformation.<sup>650</sup> The development of manifestations such as cytopenias and malignancies warrants prompt treatment in patients with IEI. (**see Table 10.5**)

### Cytopenias

Autoimmune cytopenias occur commonly in IEI<sup>10</sup> secondary to self-reacting T- and B-cells. Patients can present with a range of symptoms including emergent, life-threatening anemia or hemorrhage to mild, asymptomatic cytopenias to chronic, refractory/recurrent disease.

Blood product transfusion is indicated for the management of critical cytopenias.<sup>651</sup> Interventions to increase the safety of blood product transfusions in patients with IEI include the use of leukocyte-depletion and irradiation. Leukocyte-depletion with leukocyte filters is critical for removing cells that serve as a reservoir for latent CMV infection in donors and has been demonstrated to reduce the risk of CMV transfusion-transmission. (**see RECOMMENDATION 9.2**). Although leukocyte-depletion is common practice in most blood centers, the use of irradiation is reserved for cases where the recipient is at risk for transfusion-associated graft-versus-host disease (TA-GvHD), a complication resulting from allogeneic attack from passenger donor T-cells.<sup>652</sup> TA-GvHD risk is increased when the recipient has compromised T-cell function and when the donor has shared HLA-haplotypes with the recipient. These recommendations apply to whole blood, packed red blood cells, platelets, and fresh plasma products, but irradiation is not required for cryoprecipitate, fresh frozen plasma, or fractionated plasma products.<sup>652</sup>

Glucocorticoids represent the first line therapy for autoimmune anemia and for autoimmune thrombocytopenia. Second line therapies for refractory cases or in patients who require prolonged high doses of glucocorticoids, include immunosuppressive agents, monoclonal antibody targeting B cells and splenectomy. B cell depletion has demonstrated good initial response rates but high rates of relapse.<sup>653, 654</sup> Use of serotherapy against B cells may result in prolonged B cell aplasia or hypofunction,<sup>655, 656</sup> with increased risk for infections. Splenectomy was widely used to treat refractory cytopenias, but given the risk for sepsis and the growing list of less invasive options, removal of the spleen is rarely used in modern clinical practice.<sup>657</sup>

Most patients with autoimmune neutropenia are asymptomatic despite having very low levels of circulating neutrophils. A minority of patients with autoimmune neutropenia will develop recurrent or severe infections or stomatitis from impaired mucosal surveillance.

In these clinical scenarios, G-CSF administration has shown clinical benefit in retrospective registry analyses and is well tolerated.<sup>658</sup> As myelopoiesis is partially or fully intact in autoimmune neutropenia, clinical benefit can be achieved by small doses of 0.5-3 µg/kg/day of G-CSF given every 1-3 days to increase the ANC to a target maintenance of 1000-1500 cells/uL.<sup>659</sup> Immune suppression to treat primary autoimmune neutropenia has very limited success and is not recommended secondary to risk of infection with additional immune modulation.<sup>660</sup> Secondary autoimmune neutropenia associated with autoimmune syndromes rarely requires immune suppression solely for the low neutrophil count.

### Management of Malignancy

Current recommendations based on reports of patient cohorts do not alter standard treatment regimens in patients with IEI but consider standard regimens of shorter duration to avoid extensive periods of high infectious risk.<sup>502</sup> Patients with IEI and DNA radiation sensitivity require adjustment to standard dosing of chemotherapy and irradiation, which can cause significant short- and long-term toxicity, including later development of therapy related malignancy.<sup>661</sup> For patients with IEI but no genetic diagnosis, we recommend performing a radiation sensitivity assay prior to initiating treatment of malignancy.<sup>281</sup>

Outcomes for malignancy in IEI based on case reports and case series are inferior to immunocompetent patients and are due to advanced disease at presentation, higher risk of infections during treatment, and modifications of chemotherapy based on real or perceived risk of toxicity.<sup>650</sup> To minimize risk of infections, we suggest early consultation with infectious disease experts in immunocompromised patients and incorporation of multi-prophylactic antimicrobials and surveillance strategies, depending on the underlying IEI and oncologic therapy.

### HLH/MAS

We recommend evaluation for HLH/MAS in patients with prolonged or high fever, development or rapid progression of lymphoproliferation, unexplained rash or respiratory compromise, neurologic changes, unexplained elevation of liver enzymes or cytopenias, primary or reactivation of herpetic viral infections. Initial evaluation should include a complete blood count, complete metabolic panel, coagulation studies (PT/PTT/fibrinogen), ferritin, sIL2R, CXCL9, IL18, bone marrow biopsy, flow cytometry for perforin, CD107a mobilization, SAP and XIAP, quantitative immunoglobulins, T/B/NK cell subsets, brain MRI, and a comprehensive genetic panel for IEI and in fulfillment of the HLH2024 criteria.<sup>401</sup>

Development of extreme hyperinflammation including HLH and MAS in patients with IEI can be difficult to manage given the severity of presentation and frequent presence of other comorbidities such as infections or underlying organ dysfunction. A multi-disciplinary care team including immunology, hematology/oncology, rheumatology, infectious disease, and other specialists can lead to improved patient care.<sup>662, 663</sup>

Depending on the etiology of hyperinflammation, optimal treatment may include antimicrobials, glucocorticoids, biologics, chemotherapy, and/or HSCT. For stable patients, we recommend deferring therapy until after complete evaluation for malignancy (imaging, bone marrow or other tissue biopsy where appropriate) and infection. Treatment of hyperinflammation without knowledge of an underlying malignancy may delay this diagnosis, while use of immune suppression in the setting of severe infection may lead to overwhelming illness. Stable patients should therefore be treated with supportive measures including antimicrobials, intravenous fluids, and close monitoring until malignancy and infection are confirmed or excluded.

**Table 10.5. Management of hematologic/oncologic disease**

Manifestation	Associated IEI	Intervention/management	Strength of Recommendation	Certainty of Evidence	References
Severe Anemia or thrombocytopenia	SCID, CID	Only irradiated, leukocyte-depleted cellular blood products	Strong	Moderate	652
Autoimmune anemia or thrombocytopenia	Antibody deficiencies, immunodysregulatory disorders	Systemic glucocorticoids	Strong	Moderate	436
		B-cell depleting therapy for severe refractory cytopenias, control of EBV-infected B cells, or significant lymphoproliferation	Strong	Low	436 656 654
		High Dose IVIG			
		Do not use splenectomy, unless splenic sequestration or severe, refractory cytopenias	Conditional	Moderate	657
Autoimmune neutropenia	Antibody deficiencies, immunodysregulatory disorders	Granulocyte-colony stimulating factor (G-CSF) to achieve an ANC of 1000-1500 cells/ul for patients with recurrent and severe infections	Conditional	Low	658 659
		Do not treat autoimmune neutropenia without infections	Strong	Moderate	660
Lymphoproliferative disorders	CID with EBV susceptibility or risk of EBV-driven malignancies	Do not treat isolated benign lymphoproliferation without organ compromise, discomfort, or significant impact on quality of life	Conditional	Very Low	662
Malignancies	All IEI	Radiation sensitivity testing prior to cancer therapy in patients with IEI without molecular diagnosis	Conditional	Low	281

		Standard treatment regimens of shorter duration	Conditional	Low	494
HLH/MAS	All IEI	Coordinated treatment by a multidisciplinary team with expertise in hyperinflammation.  Defer HLH treatment in stable patients until associated malignancy and infection have been ruled out	Strong	Low	663 662

Abbreviations: AT – Ataxia-telangiectasia; CID – Combined immunodeficiency disorder; CVID – Common variable immunodeficiency; EBV – Epstein-Barr virus; PCR – Polymerase chain reaction; PET – Positron emission tomography; SCID = Severe combined immunodeficiency disorder

## **SECTION 11: Immunizations in the Management of IEI**

### **RECOMMENDATION 11.1: We recommend the use of vaccine recommendations from local government agencies (e.g., CDC) for patients with IEI.**

Strength of Recommendation: **Strong to Conditional**

Certainty of Evidence: **Low to Very Low**

Vaccine schedules and recommendations in the United States evolve rapidly in response to emerging pathogens, review of published research, and newly available agents. Since the 2015 IEI practice parameter, novel vaccines against new pathogens and expanded serotypes have been approved by the FDA, impacting individuals with IEI and their household contacts. These include vaccines for the prevention of COVID-19, Respiratory Syncytial Virus, Herpes Zoster virus, Human Papillomavirus, *Neisseria meningococcus*, *Streptococcus pneumoniae*, and MPox. Providers are urged to refer to guidelines from local government agencies (in the US, to include the Centers for Disease Control or CDC) as the recommendations may supersede the practice parameter guidelines. The CDC works in real time via the Advisory Committee on Immunization Practices (ACIP) recommendations which includes specific guidance for individuals with IEI.

**IEI patients with severe immune defects (cellular, phagocytic, and/or humoral) should not receive live, replicating vaccines (Table 11.1).**

Live vaccines should be avoided in all infants with SCID or complete athymia.<sup>87</sup> Unfortunately, vaccine-strain infections following administration of live attenuated rotavirus to newborns with SCID have been reported, occurring prior to the implementation of routine newborn screening.<sup>87-88</sup> BCG vaccination, which is still recommended in countries with high-prevalence of tuberculosis, has also caused disseminated or localized granulomatous disease in infants with SCID, interferon gamma pathway defects, or chronic granulomatous disease.<sup>664</sup> Vaccine strain rubella

virus has been detected in skin granulomas in patients with IEI, including AT, CID, and even patients with humoral immunity defects.<sup>629</sup>

It is not necessary for household contacts to avoid administration of live vaccines, other than live oral poliovirus vaccine and live, replication competent ACAM2000 for MPox/Smallpox.<sup>85, 87</sup> If an immunocompetent infant in the household has received oral rotavirus vaccination, handwashing is recommended for one month after diaper changes to prevent from transmitting live rotavirus to household siblings with IEI. Patients with IEI should avoid direct contact with an individual's affected skin if they are suffering from a blistering rash after VZV vaccination or shingles outbreak.

Individuals with isolated T cell lymphopenia and preserved cellular and humoral function may receive live viral vaccines.

This includes infants with abnormal newborn screens indicating T cell lymphopenia (but not SCID) and pediatric patients with idiopathic T cell lymphopenia, DiGeorge Syndrome (DGS), or CHARGE syndrome.

Infants with abnormal newborn screens for SCID who do not meet criteria for SCID diagnosis are at risk for preventable infectious disease prior to routine vaccination with rotavirus, MMR, or VZV. Prolonged avoidance of vaccination in these infants may lead to undesirable outcomes as measles outbreaks continue to occur because of vaccine hesitancy,<sup>665</sup> and VZV vaccination can prevent 97% of infections in children annually in the United States.<sup>666</sup> Rotavirus infection following vaccination has only been described in infants with SCID; widespread vaccination has led to a significant decrease in hospital visits for rotavirus infections in children less than 3 years of age.<sup>667</sup>

The recommended time for administration of the first dose of rotavirus vaccine is 15 weeks of age at the latest. At this age, some infants with persistent T cell lymphopenia may have convincing evidence for intact thymic function, increasing IgA and IgG production, and normal lymphocyte proliferation studies. Genetic testing may also provide an explanation for T cell lymphopenia arising from partial defects in thymic function such as DGS, CHARGE syndrome, or heterozygous carriers of FOXP1 defects.<sup>668</sup>

Recent guidelines for children without SCID, however with T cell lymphopenia recommends administering live viral vaccines if CD4 T cells > 400 cell/uL AND CD8 T cells > 200 cells/uL AND naïve CD4 T cells > 20% of CD4 T cells.<sup>284</sup>

For patients receiving IgRT, vaccines may be considered when there is a potential gain of T cell immunity and/or lack of seroprotection in available immunoglobulin preparations.

Recent examples include mRNA based COVID-19 vaccines under emergency use authorization, and attenuated, non-replicating Mpox vaccines in at risk individuals.

During the COVID-19 pandemic patients on IgRT were given COVID-19 vaccines (prior to the emergence of serologic immunity in the IgRT products) and T cell responses and serologic responses were measurable and found to be surprisingly robust.<sup>669</sup> As such patients with IEI are strongly recommended to receive COVID-19 vaccination and consider ongoing boosters. Pemgarda® (Pemibart) is a monoclonal antibody indicated for COVID-19 prophylaxis in immunocompromised patients, ages 12 years and older, every 3 months.

A live, non-replicating, attenuated orthopoxvirus (also referred to as modified vaccinia Ankara) was approved in 2019 for protection against smallpox/mpox in individuals with high risk of infection, including those with acquired immunodeficiency from HIV. There is currently no contra-indication for immunocompromised individuals. There have not been reports of use of this vaccine in patients with IEI, but it is certainly a vaccine to consider in at risk individuals with preserved capacity for generating a T cell response to vaccination such as 22q11 deletion syndrome with T cell cytopenia.

HPV vaccination is recommended in all patients with IEI 9 to 45 years of age, including patients on IgRT, due to theoretical gain in cellular mediated immunity. About 80% of sexually active individuals will acquire genital HPV infection in their lifetime.<sup>670</sup> Protection prior to exposure through vaccination is recommended. Three doses are currently recommended for immunocompromised persons regardless of age. IgRT products do not contain adequate specific antibody titers to prevent genital HPV infection and CD4 responses rather than serologic responses are associated with clearance of primary infection. The quadrivalent vaccine is effective for stimulating T cell function against HPV.<sup>671</sup> Patients with T cell lymphopenia from a variety of causes are at risk for viral persistence.<sup>428</sup>

Seasonal influenza vaccination is recommended in patients with IEI due to the safety of influenza vaccination and the COVID-19 vaccination data indirectly supporting this recommendation. Pre-emptive administration of antiviral medications is effective for influenza, and we suggest that patients (3 months or older) with IEI and exposure to influenza receive a prescription for on demand chemoprophylaxis<sup>672</sup> in addition to vaccination.

In 2023, routine vaccination for RSV has been recommended for “at risk” adults 60-74 years, all individuals older than 75 years-old,<sup>673</sup> and pregnant women to prevent infection in infants.<sup>674</sup> In the same year, RSV monoclonal antibody infusions for toddlers were approved up to 24 months of age.<sup>675</sup> The approach to vaccinate pregnant women or administer monoclonal antibody infusions in non-protected infants also applies for families affected by IEI.

For patients with IEI that do not require IgRT, vaccinations with conjugate vaccines may be recommended outside of the typical vaccination schedule. Patients with asplenia, TLR pathway defects, or complement deficiency require confirmation of childhood

vaccination followed by administration of booster vaccines against pneumococcal (PCV20 or PPSV23) and meningococcal (A, C, Y, W135 and B) infections. Administration of meningitis vaccines are recommended at diagnosis for asplenia and complement deficiency.

Because of the complexity and rapid evolution of recommendations for pneumococcal vaccination of the general population including those with special healthcare needs, the CDC has developed algorithmic tools to assist providers with decision making around pneumococcal vaccines. (See RECOMMENDATION 4.6)

We recommend that patients with IEI who no longer require IgRT (i.e., THI) receive live viral vaccines according to catchup schedule, at least 4 weeks after their last IgG infusion.

Shingles prevention:

Since 2017, a recombinant subunit varicella zoster vaccine (RZV) has replaced an attenuated live viral vaccine to prevent shingles in adults 50 years and older with up to 97% efficacy; in 2021, the recombinant subunit varicella zoster vaccine (RZV) was approved for administration to immunocompromised adults 19 and older. Immunologists should routinely check guidelines for the lowering of this age as immunocompromised teenagers with a history of prior live viral varicella vaccination or wild-type varicella infection may benefit.<sup>676, 677</sup> The effectiveness of the RZV in individuals with IEI is unknown; however, those who have received a previous live viral vaccine in childhood or had wild-type varicella infection are at higher risk for reactivation which may be preventable with the RZV administration. Thus, RZV is recommended for adult patients with IEI (particularly defects in NK or CTL function) that may still have preserved humoral and/or CD4<sup>+</sup> T cell function.<sup>87</sup>

The RZV vaccine is not approved at the current time for the prevention of primary varicella infection in patients who have been exposed to live varicella zoster virus from a community outbreak of varicella or direct contact with a person experiencing a shingles outbreak. For these exposures, patients with IEI may receive passive immunization via Varicella Zoster Immune Globulin (VZIG).<sup>678</sup> Patients receiving IgRT are likely protected if IVIG is given within 3 weeks of exposure.<sup>679</sup>

**Table 11.1. Vaccination considerations in IEI**

Vaccination approaches	Associated IEI	Vaccines of relevance	Strength of recommendation	Certainty of evidence	References
------------------------	----------------	-----------------------	----------------------------	-----------------------	------------

CONTRA-INDICATED	Severe IEI - including SCID, CID, IFN- $\alpha$ deficiency, IFN- $\gamma$ deficiency, IL-12 axis deficiencies, antibody deficiencies and CGD	All live viral vaccines, live attenuated Influenza vaccination (LAIV), Dengue  All live bacterial (BCG, typhoid)	Strong	Low	87 664 384
Active vaccination while receiving IgRT: Target vaccine preventable diseases	Patients with IEI with adequate T cell function AND receiving IgRT	mRNA vaccines, e.g., COVID-19 emerging strains	Conditional	Low	669
		HPV vaccines	Conditional	Very Low	671
		Seasonal inactivated vaccines, e.g., Influenza	Conditional	Low	680
		Recombinant zoster vaccine for shingles	Conditional	Very Low	676 677
Vaccination and boosters with conjugated vaccines for patients at risk for severe bacterial infections	Complement deficiencies  Asplenia/Hyposplenism  TLR defects	Early administration of MenACWY (less than 5 yrs); followed by boosters with MenACWY +  MenB vaccination, or pentavalent meningococcal vaccine  Primary vaccination or completion of primary series with conjugated pneumococcal vaccines	Strong	Low	87
Catch up and “booster” vaccines for patients at risk for serious and/or chronic viral infections	Defects in cytotoxic T cells; NK cell deficiencies	HPV vaccines	Conditional	Very Low	330
		Recombinant zoster vaccine for shingles	Strong	Very Low	676 677
Vaccination of household contacts of	Household contacts of any patient with IEI	Scheduled routine vaccinations are encouraged, including routine live viral vaccines, except oral polio vaccine	Strong	Low	85 87 284

patients with IEI		and ACAM2000 Mpox vaccine

## **SECTION 12: Immune Reconstitution Therapy for IEI**

**RECOMMENDATION 12.1: We suggest that allogeneic HSCT for patients with IEI be performed at a center with experience in HSCT for IEI.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Moderate**

Since 1968, allogeneic HSCT has become a widely used definitive treatment for patients with severe forms of IEI. The 5-year overall survival (OS) for patients with IEI receiving allogeneic HSCT can be approximated at 80%,<sup>681</sup> but this estimate varies depending on the underlying IEI, donor-patient human leukocyte antigen (HLA) match, myeloablation approach, stem cell source, patient age, performance status and co-morbidities. The indication for specific genetic disorders and the approaches and timing of HSCT are variable depending on individual IEI. For example, allogeneic HSCT is universally recommended for patients with SCID, and transplant outcomes are superior for patients transplanted before 3.5 months of age to minimize the risk of acquiring infection prior to HSCT.<sup>82</sup> In contrast, patients with diseases of immune dysregulation such as *LRBA* deficiency or *CTLA4* haploinsufficiency are typically only considered for allogeneic HSCT once the disease expression in patients has proven to be severe.<sup>682</sup> HSCT for IEI associated with radiation sensitivity and chemosensitivity necessitate the use of minimal-intensity conditioning regimens to reduce risk of toxicity.

An in-depth knowledge and active clinical practice in IEI are required for treating clinicians and HSCT teams to remain abreast of currently accepted or preferred practices for patients with IEI as they evolve.<sup>683</sup>

**RECOMMENDATION 12.2: We recommend that patients with typical SCID or leaky/atypical SCID receive definitive therapy with allogeneic HSCT or gene therapy.**

Strength of recommendation: **Strong**

Certainty of evidence: **High**

Patients with SCID require definitive treatment with allogeneic HSCT or gene therapy to survive beyond 1-2 years of age.<sup>56</sup> HSCT outcomes are optimal for patients diagnosed by newborn screening with greater than 90% overall survival (OS).<sup>60</sup> Survival has repeatedly been demonstrated to be superior for patients transplanted before the age of 3.5 months, which can be considered as a surrogate for lack of infection.<sup>59, 82, 684</sup>

For patients with SCID, the decision to proceed to allogeneic HSCT is straight-forward. (See Section 2).<sup>82</sup> HSCT for patients with severe T cell lymphopenia without a genetic diagnosis may be deferred because of the potential improvement of T cell numbers over time. Patients with congenital athymia should be treated with cultured thymus tissue implantation (CTTI) (see RECOMMENDATION 12.3).<sup>83</sup>

For SCID patients undergoing allogeneic HSCT, the use of pretransplant myeloablative conditioning regimen is associated with improved B cell reconstitution,<sup>684</sup> but other factors should be considered regarding the treatment approach such as the presence of active infection, donor and recipient HLA-matching, graft type, and underlying genetic disorder. Importantly, SCID patients who have genetic variants associated with radiation and chemotherapy sensitivity should receive treatment with reduced doses of alkylator-based conditioning agents, in order to decrease the risk of late effects such as poor growth, failure of development of secondary dentition, autoimmunity and malignancy.

Gene therapy is another option for SCID patients with pathogenic variants in certain genes, for example *ADA*, *IL2RG*, *DCLRE1C* and *RAG1*, through enrollment in open clinical trials. Gene therapy offers immune reconstitution without the risk of graft versus host disease (GVHD) associated with allogeneic HSCT. SCID is ideally suited to gene therapy given the survival advantage of T cells expressing the normal gene. The first gene therapy trials for SCID were performed in patients with X-linked SCID and used gammaretroviral vectors. Despite early successes in T cell reconstitution and patient survival, the development of T-cell acute lymphoblastic leukemia due to insertional mutagenesis tempered early successes, and these vectors were abandoned.<sup>685</sup> Self-inactivating (SIN) gammaretroviral and lentiviral vectors were later developed, with modification of viral promoters and enhancers to reduce the risk of malignancy.<sup>686</sup> Recent clinical trials have incorporated low-exposure/non-myeloablative conditioning to facilitate the engraftment of hematopoietic stem cells and the development of immune cells other than T cells. The numbers of gene-corrected stem cells and the vector copy number influence T cell reconstitution and are being optimized. At the time of writing, clinical trials utilizing lentiviral vectors were open for X-linked SCID (NCT03601286, NCT04286815), ADA-SCID (NCT05432310), Artemis SCID (NCT03538899), and RAG1 SCID (NCT04797260) patients who lack an HLA-matched related donor. Some trials also exclude patients with an HLA-matched unrelated donor. Remarkably, 5-year OS for healthy patients with ADA SCID treated with gene therapy or allogeneic HSCT after the year 2000 are similar, both greater than 90%.<sup>81</sup>

**RECOMMENDATION 12.3: We recommend that patients with congenital athymia disorders be treated with cultured thymus tissue implantation (CTTI).**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

The treatment of patients with congenital athymia with cultured thymus tissue implantation (CTTI) at the time of writing is clinically available at Duke Health Center (North Carolina, US) and Great Ormond Street Hospital (London, UK). T cell reconstitution, sufficient to prevent overwhelming infections, typically develops 6 to 12 months following CTTI. Two-year survival among 95 patients with congenital athymia treated with CTTI was 76%.<sup>83, 687</sup> CTTI should be pursued, when possible, in all patients with severe congenital athymia disorders (e.g., 22q11 deletion syndrome, CHD7 deficiency, TBX1 deficiency, FOXP1 deficiency, and PAX1 deficiency). BMT with a matched sibling donor, when available, has been suggested as a temporary alternative form of immune reconstitution; however, evidence is limited.<sup>688-690</sup>

**RECOMMENDATION 12.4: We recommend that patients with CID disorders who have severe cellular immune defects or who manifest severe or refractory disease complications be considered for allogeneic HSCT.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

Decisions regarding allogeneic HSCT for CID are made based on both the genetic disorder and individual presentation. CID disorders are heterogeneous, and patient phenotypes can range from mild to severe. Clinicians should gauge the pathogenicity of the genetic variant for CID disorders that have multiple mechanisms of disease and the range of phenotypes, such as *IKZF1* deficiency.<sup>691, 692</sup> Additionally, care should be given to whether CID disease manifestations can be corrected by replacement of hematopoietic stem cells and derived lymphocyte populations.<sup>693</sup> Allogeneic HSCT decisions should be directed by physicians experienced in the care of patients with IEI. Shared decision making with families and patients is also needed given the diversity of management options for most CID disorders. Recent experience suggests that allogeneic HSCT outcomes are better for patients treated at young ages, without severe disease complications, than older patients. Among 130 patients with CD40L deficiency studied, 5-year OS for patients transplanted after the year 2000 was 90% or higher for patients less than 5 years of age and for patients without organ damage, liver disease, or *Cryptosporidium* species infection. Survival for patients older than 10 years of age or with these comorbidities ranged from approximately 40-60%.<sup>694</sup> For DOCK8 deficiency, a multicenter cohort of 81 patients exhibited 2-year OS of 84%. Patients transplanted after 2010 had an improved 2-year OS of 92%, and there was a trend towards better survival for patients who received HSCT before 8 years of age, 96% versus 78% in older patients.<sup>695</sup> Over 100 patients with MHC Class II deficiency have been treated with allogeneic HSCT with OS ranging between 66–100% in more recent years, and outcomes appear better in patients transplanted before the age of 2 years.<sup>696</sup>

Allogeneic HSCT can be curative for patients with WAS, and HSCT is recommended to prevent the severe disease complications of WAS. Survival outcomes following

allogeneic HSCT are highest for patients transplanted at a young age, usually less than 2-5 years of age. Five-year OS in patients transplanted younger than 5 years of age is reported to be greater than 90%.<sup>697</sup> Patients should be treated with conditioning regimens that achieve myeloablation, such as reduced toxicity busulfan-containing regimens, with the goal of obtaining stable myeloid donor chimerism >50% as lower levels are associated with increased risk of thrombocytopenia and the development of autoimmunity following HSCT.<sup>697</sup>

Allogeneic HSCT is often considered for patients with CID disorders when they present severe disease manifestations, such as NEMO deficiency and cartilage-hair hypoplasia (CHH).<sup>698, 699</sup> OS after HSCT in a cohort of 29 patients with NEMO deficiency was 74%, with greater than 90% survival for patients who received grafts from matched sibling donors and for patients who did not have mycobacterial infection. HSCT may not cure colitis because of cell-intrinsic abnormalities of epithelial cells. Reported survival outcomes following allogeneic HSCT in patients with CHH from several case series range from 63 to 100%.<sup>699</sup>

**RECOMMENDATION 12.5: We recommend that patients with primary HLH disorders, and patients with X-linked lymphoproliferative disease type 1 be evaluated for allogeneic HSCT.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

Patients with familial HLH due to pathogenic variants in *PRF1*, *UNC13D*, *STX11*, and *STXBP2* should be offered allogeneic HSCT due to the clinical severity.<sup>700</sup> Patients with HLH associated with Griscelli syndrome type 2 due to pathogenic variants in *RAB27A*, are often treated with allogeneic HSCT, even without obvious pigmentary defects.<sup>701</sup> Decision to HSCT in patients with Chediak-Higashi syndrome should take results of genetic testing and cytotoxicity assay results into account along with the clinical phenotype.<sup>702</sup> The risk of HLH is low in patients with Hermansky-Pudlak syndrome type 2, and HSCT is typically not justified.<sup>703</sup> Patients with XLP1 are offered allogeneic HSCT due to the high risks of fatal HLH associated with EBV infection along with the risks of lymphoma, humoral deficiency, vasculitis, and other rare complications.<sup>704</sup> Patients with XIAP deficiency have a wide phenotypic variability and allogeneic HSCT should be reserved for patients who manifest severe recurrent or refractory HLH, IBD, or other serious complications.<sup>705</sup> Of note, deficiency of XIAP confers higher risk of severe GVHD, and aggressive measures should be taken to prevent GVHD.<sup>706</sup>

For all patients, allogeneic HSCT is ideally performed once HLH is in remission, as active HLH confers a negative effect on survival. However, allogeneic HSCT should not be delayed if complete remission seems unlikely. Allogeneic HSCT should be performed in patients with isolated central nervous system HLH.<sup>708</sup> Asymptomatic siblings identified due to family history should be offered HSCT, as outcomes are

superior prior to onset of HLH symptoms.<sup>709, 710</sup> Fully myeloablative conditioning regimens (such as full myeloablative busulfan and cyclophosphamide) are avoided in patients with HLH because of a high risk of complications such as hepatic veno-occlusive disease, pulmonary hemorrhage, and low survival.<sup>711</sup> Reduced intensity conditioning regimens incorporating melphalan or treosulfan and fludarabine were implemented as an alternative with greater than 80% survival but have fallen out of favor due to high rates of mixed chimerism and eventual secondary graft failures.<sup>712</sup> A European study reported 100% OS at a median follow up of 36 months for patients treated with busulfan and fludarabine.<sup>713</sup>

**RECOMMENDATION 12.6: We suggest that patients with immune dysregulation who manifest severe or refractory disease complications be evaluated for allogeneic HSCT**

Strength of recommendation: **Conditional**

Certainty of evidence: **Moderate**

Patients with IEI classified by the IUIS as diseases of immune dysregulation with autoimmunity can be challenging to treat with allogeneic HSCT due to the significant pre-treatment complications, the potential need to control the underlying immune dysregulation prior to HSCT and variability in the tissue expression of causative genes. There is currently limited experience for most immune dysregulation disorders, and the outcomes are variable. Approaches to HSCT should be discussed with an understanding of the underlying genetic disorder and whether allogeneic HSCT would correct it, along with knowledge of the success of allogeneic HSCT versus conventional treatments.

Despite the limited number of patients reported, patients with IL-10R and IL-10 deficiencies appear to do well following allogeneic HSCT, which may relate to the relatively young age at transplant, having disease generally limited to the GI tract, and predominantly more recent years of transplant.<sup>714, 715</sup> Of note, it is important to identify a genetic etiology in patients with very early onset IBD and early onset IBD, as allogeneic HSCT would not be indicated in patients with epithelial defects that are responsible for disease.<sup>312</sup>

Survival for patients with immune dysregulatory disorders is variable and, in some cases, long-term OS after allogeneic HSCT can appear similar to that reported for conventional therapies. A study of long-term outcomes for IPEX patients observed a 15-year survival rate of 73% for patients treated with allogeneic HSCT (N=58) and 86% for patients treated with immune suppression only (N=34).<sup>716</sup> However, new autoimmune problems continued to develop in 51% of patients treated with immune suppression compared to only 17% of transplanted patients. Notably, patients with low disease scores had significantly better survival, greater than 80%. Reported allogeneic HSCT survival among 18 patients with CTLA-4 haploinsufficiency was 73%,<sup>682</sup> and among 23

patients with STAT3 GOF was 62%.<sup>447</sup> While reported outcomes are not high, outcomes are likely to improve with time as pre-HSCT targeted treatments and conditioning approaches are being tailored for these disorders, and allogeneic HSCT being performed at younger ages before accumulation of co-morbidities.

Not all immune dysregulatory disorders should be considered for allogeneic HSCT. For instance, allogeneic HSCT is not indicated in patients with pathogenic variants in *AIRE*. *AIRE* is expressed in the thymus and is involved in the expression of tissue-restricted antigens that are essential for negative selection and elimination of autoreactive T cells.<sup>408</sup> Patients with ALPS are usually manageable with sirolimus or other treatments and are not typically considered for allogeneic HSCT.<sup>717</sup>

Allogeneic HSCT may be indicated in a small subset of autoinflammatory disorders that are severe and not refractory to conventional treatment. Outcomes for patients with ADA2 deficiency appear excellent, with 2-year OS of 97% and GVHD-free, rejection-free survival of 73%.<sup>718</sup> Notably, allogeneic HSCT prevented new vascular complications.

**RECOMMENDATION 12.7: We recommend allogeneic HSCT for patients with defects in neutrophil number and function associated with severe clinical phenotypes**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

Most patients with LAD Types I and III and with CGD are considered for allogeneic HSCT due to the severity of disease complications and long-standing HSCT experience. The largest multi-center retrospective cohort analysis of outcomes in LAD Types I (N=69) and III (N=11) reported 83% 3-year OS.<sup>719</sup> Survival was greater than >90% for patients with a fully matched related or unrelated donor and for patients transplanted in infancy.<sup>719</sup> Data from the Inborn Errors Working Party (IEWP) of the European Society for Blood and Marrow Transplantation (EBMT) on 712 patients with CGD demonstrated a 3-year OS of 85.7%.<sup>720</sup> Survival was greater for patients transplanted before the age of 18 years and for patients with HLA-matched donors.<sup>720</sup> Data from the PIDTC also demonstrated excellent outcomes among 400 patients with CGD, with 3-year OS of 82% and superior survival with HLA-matched donors.<sup>721</sup>

Definitive treatment of patients with other congenital defects of phagocyte number or function is more variable. Many patients may be managed with conservative treatments such as G-CSF and prophylactic antimicrobials.

**RECOMMENDATION 12.8: We suggest allogeneic HSCT in patients with innate immunity defects affecting hematopoietic cell lineages and who manifest with recurrent and persistent severe infections.**

Strength of recommendation: **Conditional**

Certainty of evidence: **Low**

Patients with disorders classified as defects in intrinsic and innate immunity who have severe disorders or severe phenotypes can be considered for treatment with allogeneic HSCT. Patients with severe forms of Mendelian Susceptibility to Mycobacterial Disease including complete *IFNGR1* and *IFNGR2* deficiencies are usually considered for allogeneic HSCT however; mortality and graft failure are relatively high in these patients, often related to disseminated mycobacterial disease and to high levels of endogenous interferon gamma that contribute to graft rejection.<sup>722</sup> A review of 12 cases of IFN-γR1 deficiency noted only four successful transplantations,<sup>723</sup> and a single center series of 7 patients with IFN-γR2 deficiency reported 71% event-free survival.<sup>724</sup> Similarly, patients with STAT1 GOF may have severe disease that is indication for allogeneic HSCT, but current experience suggests challenges related to inflammation, graft failure, and suboptimal outcomes in these patients.<sup>725</sup> Strategies to mitigate the effects of interferon gamma may improve transplant outcomes in these patients.<sup>726</sup>

Patients with congenital neutropenia or Schwachman-Diamond syndrome who develop myelodysplastic syndrome (MDS), leukemia, or other bone marrow diseases can be treated with allogeneic HSCT. 5-10% of MDS patients will develop aplastic anemia, 20-33% will develop cytogenetic abnormalities or MDS, and 12% to 25% will transform into leukemia and require allogeneic HSCT.<sup>727, 728</sup> Several studies have reported superior survival for patients with marrow failure (70-80%) versus those with MDS/AML (15-40%).<sup>729, 730</sup> Outcomes also appear superior for patients with MDS compared with AML, suggesting that marrow surveillance for identification of early stages of clonal evolution may be indicated.<sup>731</sup> Patients with GATA2 deficiency can be treated with HSCT based on the development of severe infectious complications or bone marrow abnormalities including MDS. A series of 22 patients treated at a single center for MDS or AML; reported 2-year OS of 86%,<sup>732</sup> and a series of 65 patients with MDS reported 5-year OS of 75%.<sup>733</sup>

**RECOMMENDATION 12.9: We recommend that any patient with IEI who receives definitive treatment with allogeneic HSCT, CTTI, or gene therapy receive life-long follow-up by clinicians experienced in evaluating immune reconstitution and monitoring for long-term complications of these procedures.**

Strength of recommendation: **Strong**

Certainty of evidence: **Moderate**

Survivors of allogeneic HSCT and other definitive therapies require continued care beyond the first year following definitive treatment. Evaluation of immune reconstitution during the first 2 years following treatment is critical. Even patients without IEI who receive allogeneic HSCT may have impaired immune function following HSCT.<sup>734</sup> Evaluation of immune reconstitution facilitates decisions regarding ending isolation practices, withdrawing prophylactic antimicrobial medications, and beginning routine

post-HSCT vaccinations. Complete immune reconstitution following allogeneic HSCT is estimated to occur within 1-2 years, or sooner, in the absence of GVHD. Recommendations exist regarding vaccination strategies for HSCT patients in general and for patients with specific IEI, such as SCID. Initiation of vaccine schedules is guided by time post-HSCT or, preferably, by immunology evaluation.<sup>735-737</sup> Patients may have prolonged deficient adaptive immunity and therefore live vaccines should not be given to patients after HSCT without confirmation of their immune competence. T cell reconstitution sufficient to prevent infections typically develops by a year following CTTI, and guidance regarding vaccination of patients who received CTTI is available.<sup>83, 738</sup>

Patients who receive definitive treatments require continued clinical monitoring throughout their lifetime for late effects of allogeneic HSCT and for underlying disease-specific complications not addressed by the definitive therapy. Late deaths more than 2 years post HSCT can occur in patients with IEI, highlighting the need for lifetime follow-up.<sup>739-741</sup>

## **SECTION 13: PRECISION MEDICINE**

**RECOMMENDATION 13.1: We recommend the use of targeted therapies to treat IEI based on an identified molecular defect or a clinical phenotype suggestive of a defect in host immune responses.**

Strength of recommendation: **Conditional to Strong**

Quality of evidence: **Low to High**

Advances in the immunopathogenic mechanisms of IEI have led to the development of targeted therapies, which is also referred as Precision Medicine. (**Table 13.1**) Several of these medications are currently approved by the FDA. (**Table 13.2**)

*JAK inhibitor therapy for patients with JAK/STAT gain of function mutations.*

Evidence supporting the use of JAK inhibitors for IEI is limited, and there are no clinical trials to date. However, for monogenic JAK/STAT disorders, early introduction of JAK inhibitor therapy can be essential for partial or complete resolution of disease.

JAK/STAT signaling pathway causes engagement of one of four JAK proteins, which phosphorylate and recruit one of seven STAT proteins (STAT1, STAT2, STAT3, STAT4, STAT5a, STAT5b, STAT6). Once phosphorylated, dimerized STAT translocates to the nucleus and regulates gene expression. JAK inhibitors are now approved for a variety of disorders including myelofibrosis, polycythemia vera, rheumatoid arthritis, inflammatory bowel disease, psoriasis and psoriatic arthritis, eczema, alopecia, and acute graft vs. host disease. Mechanistic studies and cohort case reports have shown partial or complete response to treatment in JAK/STAT GOF disorders, specifically STAT1 GOF and STAT3 GOF.<sup>447, 587, 742-751</sup> JAK inhibitors have also shown clinical efficacy in cohort studies and case reports in treating interferonopathies (**Table 13.1**).<sup>752-757</sup>

JAK inhibitors are administered starting with the recommended dose for FDA approved indications and titrated every 4-6 weeks based on clinical response. There are no prospective studies to indicate optimal dosing for each JAK inhibitor, and dosing regimens are limited to cohort and case reports. Based on the retrospective experiences, ruxolitinib treatment is started at a dose of 15 mg/m<sup>2</sup>/dose twice daily and increased to 30 mg/m<sup>2</sup>/dose twice daily, maximal dose is 25 mg twice a day. 50 mg/m<sup>2</sup>/dose has been tolerated in children, but the long-term data on high dose is not adequate to recommend this dose longitudinally.<sup>758</sup> Baricitinib may be used 2 mg daily and increased to 4 mg daily within 4-6 weeks, again according to clinical response and tolerance. In children under 9 years, use 2 mg per day<sup>759</sup> Dose escalation of 25% weekly until goal dose is achieved is suggested.<sup>589</sup> Given the increased risk for herpes virus Infections, prophylaxis with acyclovir is suggested.<sup>589</sup> Clinical assessments should be taken every 4 to 6 months for opportunistic infections,<sup>447, 589</sup> cardiovascular disease, thromboembolic disease, malignancy, or severe liver disease.<sup>447</sup>

#### ADA-ERT for patients with ADA deficiency

Elepegademase is an FDA-approved recombinant, polyethylene-glycol conjugated bovine adenosine deaminase enzyme replacement therapy (ADA-ERT) and has been successfully used in ADA deficient patients, resulting in improvement in lymphocyte counts, absolute neutrophil counts, and reduction in infections. Elepegademase has a half-life of 3 days and has been demonstrated to reduce plasma deoxyadenosine levels to <0.02 mmol/L within 3-6 months.<sup>760-762</sup> Rare adverse reactions include cough, vomiting, diarrhea, and minor injection site reactions. Initiation of ADA-ERT should be prompt upon diagnosis of ADA deficiency and does not require waiting for genetic diagnosis, if absence of enzyme activity is demonstrated. Initial dosing is 0.4 mg/kg/week intramuscularly in infants with ADA-SCID, which is divided into two doses per week. Longitudinal monitoring of plasma ADA levels, erythrocyte deoxyAXP levels, as well as blood counts and lymphocyte subsets should be performed at least every six months to ensure adequate response. Up dosing by 0.033 mg/kg/week is recommended if trough plasma ADA level remains <30 mmol/hr/L or if trough dAXP exceeds 0.02mmol/L. In patients with ADA deficiency-associated pulmonary alveolar proteinosis or idiopathic hepatitis, higher doses of ADA-ERT may be needed for clinical responses. In older children and adolescents, dosing of 0.2 mg/kg/week is recommended to maintain trough plasma ADA levels >30 mmol/hr/L, which may be given in a single dose weekly. There are no contraindications to ADA-ERT therapy. Known medication interactions include vidarabine, which is a substrate for ADA, and 2-deoxycoformycin, which is a potent inhibitor of ADA. As ADA-ERT does not result in full immune reconstitution, antimicrobial prophylaxis and IgRT might also be used for patients on ADA-ERT. Restoration of antibody function was demonstrated in patients receiving bovine-derived ADA-ERT, and waning of antibody function and B cell oligoclonality has been described in patients on long-term therapy. Furthermore,

reduced efficacy has been observed with long-term therapy with bovine-derived ADA-ERT, which may be due in part to development of neutralizing antibodies. Serious events including EBV-associated lymphoproliferative disease, thyroid carcinoma, and lymphomas have also been described in patients on long-term ADA-ERT. Accordingly, ADA-ERT should be a bridging therapy prior to curative treatments such as allogeneic HSCT.

#### CTLA4-Immunoglobulin for patients with CTLA4 haploinsufficiency and LRBA deficiency.

CTLA4 is an inhibitor checkpoint protein that works in competition with the costimulatory molecule CD28 for the ligands CD80 and CD86. LRBA is essential for intracellular recycling of proteins, including CTLA4. Abatacept and belatacept are recombinant fusion proteins of CTLA-4 and human IgG1 that stop T cell activation by blocking CD28 engagement and T cell activation.<sup>763</sup> Abatacept has been shown to induce improvement in symptoms in patients with CTLA4 haploinsufficiency.<sup>682, 764</sup> A case series of subjects with LRBA deficiency showed that 3 of the subjects who experienced severe interstitial lung disease, refractory to other medications, experienced an improvement in pulmonary function after abatacept treatment, apparent within 6 months of starting treatment.<sup>763</sup> Long term follow up of patients with LRBA deficiency on abatacept showed improvement in chronic diarrhea, lymphoproliferation, and autoimmune cytopenia. Circulating T follicular helper cells (cTfh) and soluble CD25 were reliable biomarkers, decreasing while on abatacept in most patients.<sup>764</sup>

#### IL-1 inhibition

Three drugs targeting the IL-1 pathway are currently approved by the FDA: anakinra (recombinant form of IL-1R antagonist), rilonacept (recombinant IL-1R that binds to IL-1 $\alpha$ , IL-1 $\beta$  and IL-1RA), and canakinumab (human monoclonal antibody that binds to IL-1 $\beta$ ). All have been shown to reduce symptoms, inflammatory markers, serum amyloid A and neutrophil counts in patients with IEI due to excess IL-1 signaling. The therapies differ by international disease indications and regulatory approvals, as well as cost and availability. These drugs have different half-lives that may affect clinical and patient preference: anakinra has a terminal half-life of 4-6 hours, rilonacept has a half-life of approximately 7 days, and canakinumab is the longest at 22.9 to 25.7 days. Anakinra may have improved central nervous system penetration.<sup>765</sup> For all IL-1 targeted therapies, higher doses may be required in pediatric subjects. In addition, data on safety and efficacy in pregnant or breastfeeding patients is limited. To avoid delays associated with achieving a molecular diagnosis and the associated morbidity, a trial of IL-1 blockade with anakinra, rilonacept, or canakinumab may aid in the diagnosis of IL-1 mediated disorders.<sup>766</sup>

IL-1 inhibitors are used for treatment of patients with periodic fever syndromes with increased inflammation due to cryopyrin associated periodic syndrome, hyper IgD, or

familial mediterranean fever (FMF) unresponsive to colchicine, or TNF receptor associated periodic syndrome (TRAPS) which is also associated with increased IL-1 release. Therapeutic targeting and dosing based on severity of disease may improve efficacy. Patients with severe phenotypes require higher doses than patients with mild disease.<sup>767,768</sup> Long term studies of each of the therapies independently demonstrate a favorable safety profile, reduction in symptoms, and improved quality of life in children and adults.<sup>767-772</sup>

Randomized controlled trials of canakinumab in FMF showed resolution of baseline flares in greater than 80% of patients, with approximately 60% showing complete resolution. Increased dosing from 150 mg every 4 weeks to 300 mg every 4 weeks led to complete response in greater than 70% of participants.<sup>768</sup> Notably anti-IL-1 blockade is efficacious in reducing proteinuria.<sup>768</sup> Long-term efficacy of both anakinra and canakinumab has been reported for patients with colchicine-resistant FMF.<sup>771, 772</sup> A randomized controlled trial of canakinumab in mevalonate kinase deficiency showed resolution of baseline flares in 60% of patients, with 35% showing complete resolution. Increased dosing led to resolution in 57% of participants.<sup>768</sup> In 8 patients with less severe disease and normal inflammatory markers between inflammatory episodes, on-demand anakinra was effective for reducing frequency or length of episodes by greater than 50%.<sup>773</sup> A randomized controlled trial of canakinumab in TRAPS showed resolution of baseline flares in >60% of patients, with 45% showing complete resolution. Increased dosing led to clinical responses in greater than 73% of participants.<sup>767</sup> Long term studies of canakinumab demonstrate a favorable safety profile, reduction in symptoms, and improved quality of life in children and adults.<sup>768-774</sup>

Anakinra and canakinumab have been effective in patients with certain variants in *PSTPIP1*, causing PAPA syndrome.<sup>775, 776</sup> Homozygous mutations in *LPIN2* are associated with Majeed syndrome, a chronic recurrent multifocal osteomyelitis phenotype with congenital dyserythropoietic anemia and interventions, primarily with anakinra, have been shown to reduce systemic inflammatory markers and sterile osteomyelitis in affected individuals.<sup>777-779</sup> IL-1 treatment for patients with missense mutations in *NLRP12* has led to improvement in febrile episodes, though some patients experienced relapse of symptoms.<sup>780, 781</sup> IL-1 blockade with canakinumab or anakinra has been effective in patients with FCAS4, or mild NLRC4-AID with symptoms to cold stimuli.<sup>782, 783</sup> Treatment with anakinra reduces inflammatory episodes associated with Neonatal-Onset Cytopenia, Autoinflammation, and Recurrent Hemophagocytic lymphohistiocytosis (NOCARH).<sup>784</sup> Patients showed improvement in systemic inflammatory markers including CRP and ferritin, fever, rash, hepatosplenomegaly, and growth. The cytopenias may be less responsive to IL-1 blockade. Patients with more severe disease and features of HLH may require additional therapies or HSCT.<sup>784</sup> Use of rilonacept produces similar anti-inflammatory efficacy in patients with cryopyrin-associated syndromes.<sup>785</sup>

3898 G-CSF in neutropenia

3899 The administration of G-CSF to patients with neutropenia is summarized in **Table**  
3900 **13.1.**<sup>785-792</sup> Recombinant granulocyte-colony stimulating factor (rG-CSF) stimulates  
3901 neutrophil mobilization and delays neutrophil apoptosis.<sup>791</sup> A randomized controlled  
3902 phase 3 trial of 173 patients with severe chronic neutropenia (ANC <500 cells/uL)  
3903 showed an increase in ANC (median 1500 cells/uL), increased proportion of maturing  
3904 neutrophils within the bone marrow, and significant reduction in infection-related  
3905 events.<sup>792</sup>

3906 Plerixafor and Mavorixafor for patients with WHIM syndrome as initial therapy.

3907 Plerixafor is a small molecule antagonist of CXCR4 and has shown efficacy in treating  
3908 patients with WHIM syndrome. In clinical trials, plerixafor has been shown to reverse  
3909 panleukopenia within 1-2 weeks of initiation and reduce the burden of infections  
3910 including skin and anogenital warts due to HPV.<sup>793, 794</sup> In a phase 3 randomized cross-  
3911 over study, plerixafor was non-superior to G-CSF for reduction of infection severity  
3912 scores, but superior for resolution of leukopenia.<sup>795, 796</sup> Adverse reactions include  
3913 injection site reactions, but unlike higher dose plerixafor as used in bone marrow  
3914 transplant donors, cardiovascular and GI reactions have not been reported. Plerixafor is  
3915 teratogenic in animals and contraindicated during pregnancy. Plerixafor is administered  
3916 as a twice daily subcutaneous injection, and initial recommended dosing is 0.02-0.04  
3917 mg/kg/dose. Longitudinal monitoring of blood counts should be performed regularly to  
3918 ensure adequate response. Up dosing of 0.01 mg/kg/dose may be undertaken if, within  
3919 2-3 weeks of starting therapy, inadequate responses are seen. Antimicrobial  
3920 prophylactic therapy including IgRT is often indicated. Though restoration of IgA  
3921 production has been reported in patients receiving G-CSF therapy, no notable changes  
3922 in serum immunoglobulin levels were seen in 3 patients after 3 months of plerixafor  
3923 therapy, and antibody responses to pneumococcal and tetanus/diphtheria vaccinations  
3924 were highly variable. Mavorixafor is an oral CXCR4 antagonist approved by the FDA for  
3925 patients 12 years and older with WHIM syndrome.<sup>793</sup> Dosing is based on weight >50kg  
3926 is 400mg daily and <50kg is 300 mg daily based on the package insert. As with  
3927 plerixafor, longitudinal monitoring of blood counts should be performed regularly to  
3928 ensure adequate response. Need for IgRT should therefore be evaluated on a case-by-  
3929 case basis in patients with WHIM syndrome who are receiving plerixafor therapy.

3930 Cobalamin and folate for patients with IEI caused by defects in vitamin B12 and folate  
3931 metabolism.

3932 These defects include transcobalamin II (TCN2), solute carrier family 46 (SLC46A1;  
3933 also called the proton-coupled folate transporter), and methylenetetrahydrofolate  
3934 dehydrogenase (NADP1 dependent) 1 (MTHFD1). They present with clinical and  
3935 laboratory features of SCID including low or absent T cell proliferation following mitogen  
3936 stimulation, hypogammaglobulinemia and impaired antibody responses. These

abnormalities return to normal with folate therapy.<sup>797-800</sup> A case report of a patient with a defect in *LMBRD1*, a gene encoding a lysosomal membrane protein, also known as cblF, was described with recurrent infections, otitis media, bronchiolitis, urinary tract infections, oral candidiasis, giardiasis who had resolution of infections after treatment with cobalamin therapy.<sup>800</sup>

*IFN-γ in the treatment of mycobacterial infections in patients with IL-12p40, IL-12RB2 and IL-23R deficiency, AD partial IFN-γR1 or R2, TYK2 deficiency, IRF8 and ISG15 deficiency.*

*In vitro* data show reduced production of IFN-γ in multiple gene defects leading to increased susceptibility to invasive *Mycobacterium* spp. infections. Disorders include lack of response to IL-12 or IL-23.<sup>345, 801</sup> Patients with disseminated mycobacterial infections showed improvement after treatment with IFN-γ;<sup>802</sup> several of these patients were identified as having NEMO deficiency. Treatment with IFN-γ at 50mcg/m<sup>2</sup> in addition to anti-mycobacterial therapy have led to improvement of disseminated BCG and other mycobacterial infections in patients with IL-12RB2 deficiency and IFNγR1 deficiencies.<sup>803-805</sup>

*Fucose for treatment of lymphocyte adhesion deficiency, type II (LAD-II).*

LAD-II is a defect of fucosylation leading to loss of selectin ligands, leukocytosis, recurrent infections, as well as short stature and developmental delay. Supplementation with oral fucose has led to re-expression of selectin ligands on neutrophils with normalization of white blood cells and improvement in infections in some patients.<sup>806</sup> Discontinuation has led to loss of selectin ligands and leukocytosis.<sup>807, 808</sup>

*Leniolisib for patients with activated phosphoinositide 3-kinase delta syndrome (APDS).*

Leniolisib is a small molecule inhibitor that selectively targets hyperactive PI3K delta signaling. Leniolisib was studied in 31 patients aged 12-75 years age in an international phase 3, triple-blinded, placebo controlled with randomization 2:1 clinical trial.<sup>809</sup> Results of this trial led to FDA approval of leniolisib for the treatment of patients 12 years of age or older in 2023. Treatment with leniolisib significantly reduced lymphadenopathy and spleen size. Also noted was a decrease in elevation of transitional B cells and CD38+ plasmablasts, switched and non-switched memory B cell populations, CD8+ senescent CD57+ T cells, and CD8+ T cells including terminally differentiated effector memory (CD8+TEMRA) T cells. Overall CD4+ T cell quantities increased with reduction in CD4+TEMRA cells. Treatment with leniolisib also greatly reduced serum IgM, which is often elevated in patients with APDS.<sup>809, 810</sup>

3979

## **Section 14- Quality of Life in IEI**

**RECOMMENDATION 14.1: We recommend performing quality of life (QoL) measurements in patients with IEI, inclusive of patient reported outcome measurements (PRO) conducted with a validated tool.**

Strength of recommendation: **Strong**

Certainty of Evidence: **Moderate**

*Patient-reported outcome (PRO) instruments* are a means to capture health-related quality of life (HR-QoL) information as a measure of treatment benefits. This information comes directly from the patient, usually in the form of a questionnaire. In clinical trials, a PRO instrument can be used to measure the effect of a medical intervention on one or more *concepts* (i.e., the *thing* being measured, such as a symptom or group of symptoms, effects on a particular function or group of functions, or a group of symptoms or functions shown to measure the severity of a health condition). There are several variables (domains) in PRO instruments for measuring a person's physical health, psychological state, level of independence, social relationships, and their relationship to their environment's features. These domains in the survey instrument and the content, e.g., specific questions make the survey instrument unique for a disease category. An example is PROMIS® (Patient-Reported Outcomes Measurement Information System), a free instrument that can be used in adults and children ([www.healthmeasures.net](http://www.healthmeasures.net)).

HR-QoL instruments are usually used in clinical trials to assess changes in the patient's perspective related to any treatment effect. QoL instruments can be global such as the 36 item Short Form survey (SF-36) while others are disease specific HR-QoL instruments such as the validated Primary Antibody Deficiency-Quality of Life (PAD-QoL)<sup>812</sup> and the Common Variable Immunodeficiency Quality of Life (CVID-QoL)<sup>813</sup> instruments. The latter instruments were developed to assess disease specific associated domains that may not be captured by generic QoL instruments. The CVID-QoL survey highlighted GI and skin issues, and levels of activity, pain and discomfort.<sup>813</sup>

Many patient-reported surveys have been published examining treatment satisfaction and the comparison between IVIG and SCIG replacement therapy in patients with IEI. Most surveys have used a generic HR-QoL instrument, e.g. the Medical Outcomes Study 36-item Short Form Health Survey (SF-36), a Life Quality Index and Treatment Satisfaction Question Survey. (**Table 14.1**) Several studies have shown more favorable patient QoL among patients receiving Ig therapy at home compared to hospital or infusion center-based IgRT particularly if the IgRT is given subcutaneously (SC).<sup>814-816</sup> Patients reported greater convenience, comfort, and treatment schedule flexibility. Using the SF-36 general health questionnaire, and the Toronto Alexithymia Scale questionnaire, it was shown that the health status of adult patients with CVID was lower than those of normal subjects. Most patients (88%) were receiving IVIG every 2 or 3

weeks in a hospital setting. Overall, physical and general health scales correlated with lower clinical status, especially in females and older patients. Limitations in daily activities due to lower physical health was a major problem facing patients.<sup>816</sup> Using the SF-36 and the LQI instruments, patients showed significant improvement regardless of the form of administration of IgRT and preference for home SCIG infusions.<sup>817</sup> Prior to IgRT, CVID patients experienced diminished HR-QoL vs. the general population and a chronic disease control group.<sup>818</sup> The SF-36 and the General Health Questionnaire (GHQ-12) were used to show that almost 1/3 of CVID patients were at risk for anxiety and depression at all time points and affected two-thirds of females.<sup>512</sup> Over 6 years using the GHQ, patients perceived that their disease was getting worse over time which correlated with lower mean values of all SF-36 scales.

Using the PedsQL questionnaire, QoL was reduced in CGD patients receiving conservative management, while transplanted patients had QoL comparable to healthy children on PedsQL survey instrument.<sup>819</sup>

**RECOMMENDATION 14.2: We suggest that patient reported outcomes (PROs) should be measured using a disease-specific QoL instrument and at relevant important management changes in the patient's clinical journey.**

Strength of Recommendation: **Conditional**

Certainty of Evidence: **Low**

Health-related QoL instruments may be disease specific and change temporally with respect to treatment interventions. Some IEI such as CVID,<sup>820</sup> Ataxia-Telangiectasia,<sup>821</sup> X-linked agammaglobulinemia,<sup>822</sup> and antibody deficiencies in general<sup>823</sup> have been studied with respect to patient HR-QoL. However, many distinct IEI have not; thus, it is possible that disease-specific HR-QoL patterns of measurement will be defined to optimize care and shared decision making. Future studies investigating HR-QoL for specific IEI are warranted.

Specific interventions and diagnostic elements of relevance may include HSCT, immunoglobulin route of delivery and time from symptom onset to diagnosis.<sup>824, 825</sup> In some cases, HSCT has been reported to improve HR-QoL,<sup>824, 826</sup> however, this is not universally noted across all studies.

Delays in IEI diagnosis are expected contributors to impaired HR-QoL. Explanations for this are incomplete; however, increased organ-specific impairment is a logical and reported consequence of undiagnosed IEI.<sup>827</sup> In addition, long-term follow up by expert clinicians improves QoL. Taken together, these and other reports suggest that early and precise diagnosis can improve QoL, which has been linked to improved survival among persons with IEI.<sup>828</sup> Co-occurrence of auto-inflammatory disease has also been related to low QoL in patients with IEI and should be captured over temporal periods of disease onset and/or treatment intervention.<sup>829</sup>

**RECOMMENDATION 14.3: We suggest that IEI patients have perceived health assessed at each clinical encounter.**

Strength of Recommendation: **Conditional**

Certainty of Evidence: **Low**

Perceived health (PH) status relates to the global sense of well-being by an individual which includes physical, mental and social well-being.<sup>830</sup> Typically, PH is measured on a 5-point scale as assessed by a single question ranging from poor to excellent and is both simple and inexpensive to measure. PH is an important measure owing to the close association with overall mortality as an independent factor in a variety of disease states.<sup>831</sup> Within the realm of IEI, determinants of PH have been studied and include sleep quality,<sup>832</sup> route of immunoglobulin replacement,<sup>833</sup> hematopoietic stem cell transplant status,<sup>834</sup> and cognitive status.<sup>513</sup>

**RECOMMENDATION 14.4: We suggest that IEI patients be assessed for fatigue at each clinical encounter.**

Strength of Recommendation: **Conditional**

Certainty of Evidence: **Low**

Patients with a primary antibody deficiency<sup>517</sup> and those with CVID<sup>518</sup> commonly report fatigue as a subjective concern. Additionally, pediatric patients with IEI suffer fatigue at rates ranging from approximately 19%-65%,<sup>835</sup> which appears to be unrelated to disease activity. Clear drivers of fatigue are not evident; however, the symptom is widely found among studies examining IEI QoL,<sup>835, 836</sup> and it may be a useful prognostic feature. Since the etiology of fatigue among persons with IEI is unclear, treatment is similarly not well defined: tailored exercise prescriptions,<sup>837</sup> optimization of IgRT,<sup>838</sup> and therapeutic options for subtypes and complications of IEI<sup>839</sup> offer opportunities for improving IEI-associated fatigue.

**RECOMMENDATION 14.5: We suggest implementing shared decision making between the provider and the patient as part of clinical care to improve QoL and patient satisfaction.**

Strength of Recommendation: **Conditional**

Certainty of Evidence: **Low**

Different routes of IgRT affect HR-QoL and patient reported outcomes. Many of the HR-QoL studies comparing IVIG with SCIG suggested the latter was more acceptable to patients and improved certain aspects of HR-QoL parameters. Pulvirenti and colleagues<sup>840</sup> addressed the impact of the route of IgRT on HR-QoL using shared decision making. The first 6 months of IgRT was devoted to the education and training of CVID patients that included possible choices of IgRT administration covering such items as setting (home or infusion center), route, interval, possible adverse reactions, and interference with lifestyle patterns or needs. Patients were allowed to shift to an

alternative regimen. There was no difference on the HR-QoL with each delivery method, indicating that extensive educational attention for the patients leading to shared decision-making and individualizing patient wishes achieve the best therapeutic approach.

**Table 14.1. QoL Tools Used in IEI**

Tool	Description	Reference
Short-form 36 (SF-36) version 2.0	Generic measure of health-related QoL with 8 domains. Not specific for any disease or population.	828
Child Health Questionnaire Parent Form 50 (CHQ-PF50)	Generic measure of health-related QoL with 15 domains. Specifically designed for children 5-13 years of age.	817
Pediatric quality of Life Inventory (PedsQL 4.0)	23 item instrument for children ages 2 to 18. Scales are multidimensional for child self-report and parent proxy-report scales for healthy and acute and chronic health conditions.	819
Life Quality Index (LQI)	Measure of treatment preferences relative to enhancement of life with 4 domains. Developed for IEI patients receiving IgG.	817
General Health Questionnaire (GHQ-12)	12-item questionnaire designed to measure psychological stress and to detect depression and anxiety.	828
Treatment Satisfaction Questionnaire for Medication (TSQM)	Generic measure of treatment satisfaction with 4 domains.	838
PROMIS-29	Assess fatigue in patients with CVID	838
CVID-QoL	32 item validated HR-QOL instrument for adult patients with CVID	813
PADQOL-16	16 item validated HR-QOL instrument for adult patients with primary antibody deficiency.	812
